MEDIUM

Longest Consecutive Sequence

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Union Find](#)

Lists: Grind 169 | CodeSignal

Problem:

Given an unsorted array of integers `nums`, return the length of the longest consecutive elements sequence.

You must write an algorithm that runs in $O(n)$ time.

Example 1:

Input: `nums = [100,4,200,1,3,2]`

Output: 4

Explanation: The longest consecutive elements sequence is `[1, 2, 3, 4]`. Therefore its length is 4.

Example 2:

Input: `nums = [0,3,7,2,5,8,4,6,0,1]`

Output: 9

Example 3:

Input: `nums = [1,0,1,2]`

Output: 3

Constraints:

- $0 \leq \text{nums.length} \leq 105$
- $-109 \leq \text{nums}[i] \leq 109$

>> Brute Force [Graphs] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def longestConsecutive(self, nums):
        # Brute Force  $O(n^2)$  - for each number extend its sequence
        num_set = set(nums)
        best = 0
        for num in nums:
            length = 0
            while num + length in num_set:
                length += 1
            best = max(best, length)
        return best
```

Python

Python

```

# Python solution for Longest Consecutive Sequence

def longestConsecutive(nums):
    # Create a set from the list for O(1) look-up times
    num_set = set(nums)
    longest_streak = 0

    # Iterate through each number in the set
    for num in num_set:
        # Only start counting if 'num-1' is not present in the set
        if num - 1 not in num_set:
            current_num = num
            current_streak = 1

            # Count consecutive numbers starting from current_num
            while current_num + 1 in num_set:
                current_num += 1
                current_streak += 1

            # Update the longest streak if current one is longer
            longest_streak = max(longest_streak, current_streak)

    return longest_streak

# Example usage:

print(longestConsecutive([100, 4, 200, 1, 3, 2])) # Output: 4

```

MEDIUM

Find the Celebrity

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [Graph](#) · [Interactive](#)

Lists: Premium 98

Problem:

Suppose you are at a party with n people labeled from 0 to $n - 1$ and among them, there may exist one celebrity. The definition of a celebrity is that all the other $n - 1$ people know the celebrity, but the celebrity does not know any of them.

Now you want to find out who the celebrity is or verify that there is not one. You are only allowed to ask questions like: "Hi, A. Do you know B?" to get information about whether A knows B. You need to find out the celebrity (or verify there is not one) by asking as few questions as possible (in the asymptotic sense).

You are given an integer n and a helper function `bool knows(a, b)` that tells you whether a knows b. Implement a function `int findCelebrity(n)`. There will be exactly one celebrity if they are at the party.

Return the celebrity's label if there is a celebrity at the party. If there is no celebrity, return `-1`.

Note that the $n \times n$ 2D array `graph` given as input is not directly available to you, and instead only accessible through the helper function `knows`. `graph[i][j] == 1` represents person i knows person j , whereas `graph[i][j] == 0` represents person j does not know person i .

Example 1:

Input: graph = [[1,1,0],[0,1,0],[1,1,1]]

Output: 1

Explanation: There are three persons labeled with 0, 1 and 2. graph[i][j] = 1 means person i knows person j, otherwise graph[i][j] = 0 means person i does not know person j. The celebrity is the person labeled as 1 because both 0 and 2 know him but 1 does not know anybody.

Example 2:

Input: graph = [[1,0,1],[1,1,0],[0,1,1]]

Output: -1

Explanation: There is no celebrity.

Constraints:

- $n == \text{graph.length} == \text{graph}[i].\text{length}$
- $2 \leq n \leq 100$
- graph[i][j] is 0 or 1.
- graph[i][i] == 1

Follow up: If the maximum number of allowed calls to the API knows is $3 * n$, could you find a solution without exceeding the maximum number of calls?

Parallel Courses

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Graph](#) · [Topological Sort](#)

Lists: Premium 98

Problem:

You are given an integer n , which indicates that there are n courses labeled from 1 to n . You are also given an array `relations` where `relations[i] = [prevCoursei, nextCoursei]`, representing a prerequisite relationship between course `prevCoursei` and course `nextCoursei`: course `prevCoursei` has to be taken before course `nextCoursei`.

In one semester, you can take any number of courses as long as you have taken all the prerequisites in the previous semester for the courses you are taking.

Return the minimum number of semesters needed to take all courses. If there is no way to take all the courses, return -1 .

Example 1:

Input: $n = 3$, $\text{relations} = [[1,3],[2,3]]$

Output: 2

Explanation: The figure above represents the given graph.

In the first semester, you can take courses 1 and 2.

In the second semester, you can take course 3.

Example 2:

Input: $n = 3$, $\text{relations} = [[1,2],[2,3],[3,1]]$

Output: -1

Explanation: No course can be studied because they are prerequisites of each other.

Constraints:

- $1 \leq n \leq 5000$
- $1 \leq \text{relations.length} \leq 5000$
- $\text{relations}[i].\text{length} == 2$
- $1 \leq \text{prevCourse}_i, \text{nextCourse}_i \leq n$

- prevCoursei != nextCoursei
- All the pairs [prevCoursei, nextCoursei] are unique.

HARD

Number of Islands II

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Union Find](#) · [Matrix](#)

Lists: Premium 98

Problem:

You are given an empty 2D binary grid `grid` of size `m x n`. The grid represents a map where 0's represent water and 1's represent land. Initially, all the cells of grid are water cells (i.e., all the cells are 0's).

We may perform an add land operation which turns the water at position into a land. You are given an array `positions` where `positions[i] = [ri, ci]` is the position (ri, ci) at which we should operate the i th operation.

Return an array of integers `answer` where `answer[i]` is the number of islands after turning the cell (ri, ci) into a land.

An island is surrounded by water and is formed by connecting adjacent lands horizontally or vertically. You may assume all four edges of the grid are all surrounded by water.

Example 1:

Input: `m = 3, n = 3, positions = [[0,0],[0,1],[1,2],[2,1]]`

Output: `[1,1,2,3]`

Explanation:

Initially, the 2d grid is filled with water.

- Operation #1: `addLand(0, 0)` turns the water at `grid[0][0]` into a land. We have 1 island.
- Operation #2: `addLand(0, 1)` turns the water at `grid[0][1]` into a land. We still have 1 island.
- Operation #3: `addLand(1, 2)` turns the water at `grid[1][2]` into a land. We have 2 islands.
- Operation #4: `addLand(2, 1)` turns the water at `grid[2][1]` into a land. We have 3 islands.

Example 2:

Input: `m = 1, n = 1, positions = [[0,0]]`

Output: `[1]`

Constraints:

- $1 \leq m, n, \text{positions.length} \leq 104$
- $1 \leq m * n \leq 104$
- `positions[i].length == 2`
- $0 \leq ri < m$
- $0 \leq ci < n$

Follow up: Could you solve it in time complexity $O(k \log(mn))$, where $k == \text{positions.length}$?

String Transforms Into Another String

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Union Find](#)

Lists: Denny Zhang

Problem:

Given two strings `str1` and `str2` of the same length, determine whether you can transform `str1` into `str2` by doing zero or more conversions.

In one conversion you can convert all occurrences of one character in `str1` to any other lowercase English character.

Return true if and only if you can transform `str1` into `str2`.

Example 1:

Input: `str1 = "aabcc", str2 = "ccdee"`

Output: true

Explanation: Convert 'c' to 'e' then 'b' to 'd' then 'a' to 'c'. Note that the order of conversions matter.

Example 2:

Input: `str1 = "leetcode", str2 = "codeleet"`

Output: false

Explanation: There is no way to transform `str1` to `str2`.

Constraints:

- `1 <= str1.length == str2.length <= 104`
- `str1` and `str2` contain only lowercase English letters.

// }

```

Quick Review — Graphs 5 questions · insights · complexity · solution

#128 Longest Consecutive Sequence [Medium]

Key Insights

- Utilize a set (or hash table) for constant time look-ups.
- Only start counting a sequence from a number that is the beginning (its previous number is not in the set).
- Each number is visited only once, ensuring an $O(n)$ time complexity.
- Update the maximum sequence length as you discover longer consecutive sequences.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(n)$

Solution

We first insert all the numbers into a hash set to enable $O(1)$ membership checks. For each number in the set, we check if it is the start of a sequence by ensuring that the number minus one is not in the set. If it is the beginning, we then count all consecutive numbers following it, updating the maximum sequence length when necessary. This method guarantees that we only count each number once, satisfying the $O(n)$ time requirement.

#277 Find the Celebrity [Medium]

Key Insights

- Use pairwise comparisons to eliminate non-celebrities.
- If a candidate knows another person, the candidate cannot be the celebrity.
- Verify the candidate by checking that they do not know anyone and that everyone knows them.
- Achieve the solution in two passes: one for candidate selection and the other for validation.

Space & Time

Time Complexity: $O(n)$ – One pass for candidate selection and one for validation.

Space Complexity: $O(1)$ – Only constant extra space is used.

Solution

The approach consists of two main steps:

– Candidate Selection: Iterate through the people and maintain a candidate. For every person i , if the current candidate knows i , then set candidate = i . This works because if candidate knows i , candidate cannot be the celebrity. – Verification: Check that the candidate does not know any other person and that every other person knows the candidate. If both conditions hold, candidate is the celebrity; otherwise, return -1 .

The main data structures used are simple integer variables. The algorithm leverages a two-pass technique to reduce the number of knows API calls while ensuring correctness.

#1136 Parallel Courses [Medium]

Key Insights

- Model the problem as a directed graph where nodes are courses and edges represent prerequisites.
- Use topological sorting (Kahn's algorithm) to process courses with zero prerequisites.
- Each level (or layer) of processing represents one semester.
- Detect cycles by ensuring all courses are eventually processed; if not, a cycle exists.
- The number of BFS levels gives the minimum number of semesters necessary.

Space & Time

Time Complexity: $O(n + m)$ where n is the number of courses and m is the length of relations (prerequisites).

Space Complexity: $O(n + m)$ for storing the graph, in-degree counts, and the processing queue.

Solution

We solve the problem using a topological sort with Kahn's algorithm. First, construct a graph representation using an adjacency list and compute the in-degree for each course. Initialize a queue with courses that have no prerequisites (in-degree == 0). Then, process courses level by level. Each level processed represents one semester. For every course taken in that semester, decrease the in-degree of all its neighbors. Add any neighbor with an in-degree that becomes zero to the queue for the next semester. If, after processing, the total courses taken is less than n , then a cycle exists and return -1 . Otherwise, the number of semesters processed is the answer.

#305 Number of Islands II [Hard]

Key Insights

- Use Union Find (Disjoint Set Union) to efficiently manage connected components (islands).
- Map 2D grid coordinates to a 1D index.
- When adding a new land, check its 4 neighbors (up, down, left, right) and perform unions if they are also lands.
- Avoid duplicate processing if the same cell is added multiple times.
- Maintain a counter for islands that is updated during each union operation.

Space & Time

Time Complexity: $O(K * \alpha(m))$

n) where K is the number of operations and α is the inverse Ackermann function (almost constant time per union/find).

Space Complexity: $O(m)$

n) for storing the union-find structure.

Solution

The solution relies on the Union Find data structure to dynamically merge islands. When a new land cell is added:

- If the cell is already land, record the current island count.
- Otherwise, mark the cell as land and increment the island count.
- Check the four neighboring cells; if any neighbor is land, attempt to union the current cell with that neighbor.
- If a union actually happens (i.e., the two cells were in separate islands), decrement the island counter.
- Output the island count after each add-land operation. The key trick is converting 2D indices to a 1D representation ($r * n + c$) and using path compression along with union by rank in the Union Find implementation for optimal performance.

#1153 String Transforms Into Another String [Hard]

Key Insights

- Each character mapping from $str1$ to $str2$ must be consistent; one character in $str1$ always maps to the same character in $str2$.
- A bijective mapping is not necessary; multiple characters in $str1$ can map to the same character in $str2$.
- The order of conversions matters. When there is a cycle (e.g., mapping 'a' $\rightarrow$ 'b' and 'b' $\rightarrow$ 'a'), an intermediate unused character might be required to break the cycle.
- If $str2$ uses all 26 letters, no temporary character is available to break mapping cycles. In this case, transformation is possible only if $str1$ is already equal to $str2$.

Space & Time

Time Complexity: $O(n)$, where n is the length of the strings, because we traverse the strings to build and check the mapping.

Space Complexity: $O(1)$ or $O(26)$, which is constant space, to store the mapping for the 26 lowercase English letters.

Solution

The approach is as follows:

- If $str1$ equals $str2$, return true immediately.
- Build a mapping from each character in $str1$ to the corresponding character in $str2$. While creating the mapping, check that each character maps consistently.
- Count the number of

distinct characters in str2. If this number is 26 and str1 is not already equal to str2, it is impossible to perform the transformation because there is no spare character available as a temporary placeholder. – If the mapping is consistent and there exists at least one character not used in str2 (i.e., distinct characters in str2 is less than 26), the transformation is possible. The important trick is identifying the need for a free character when the target mapping is “full” (i.e., covers all 26 letters). Without a free character, you cannot avoid cycles where a temporary intermediate is necessary.

Longest Palindrome

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Greedy](#)

Lists: Grind 169

Problem:

Given a string *s* which consists of lowercase or uppercase letters, return the length of the longest palindrome that can be built with those letters.

Letters are case sensitive, for example, "Aa" is not considered a palindrome.

Example 1:

Input: *s* = "abcccccdd"

Output: 7

Explanation: One longest palindrome that can be built is "dccaccd", whose length is 7.

Example 2:

Input: *s* = "a"

Output: 1

Explanation: The longest palindrome that can be built is "a", whose length is 1.

Constraints:

- $1 \leq s.length \leq 2000$
- *s* consists of lowercase and/or uppercase English letters only.

[*] Greedy — Pattern Solution (stored optimal)

Python

```
# Python solution for the Longest Palindrome problem

def longestPalindrome(s: str) -> int:
    # Create a dictionary to store the frequency of each character
    char_counts = {}
    for char in s:
        # Increment the count for the character
        char_counts[char] = char_counts.get(char, 0) + 1

    # Variable to store the length of the palindrome
    palindrome_length = 0
    # Flag to indicate whether we can add one more character in the middle for an odd count
    center_added = False

    # Iterate through the character counts
    for count in char_counts.values():
        # Add the largest even number from count to palindrome_length
        palindrome_length += (count // 2) * 2
        # If count is odd and we haven't added the center character yet
        if count % 2 == 1 and not center_added:
            palindrome_length += 1
            center_added = True

    return palindrome_length

# Example usage:
print(longestPalindrome("abcccd"))
```

C++

```
// C++ solution for the Longest Palindrome problem

#include <iostream>
#include <unordered_map>
#include <string>
using namespace std;

int longestPalindrome(string s) {
    // Create a hash table to store frequency of each character
    unordered_map<char, int> charCounts;
    for (char c : s) {
        charCounts[c]++;
    }

    int palindromeLength = 0;
    bool centerAdded = false;

    // Iterate over the character counts
    for (auto &entry : charCounts) {
        int count = entry.second;
        // Add the largest even number from count
        palindromeLength += (count / 2) * 2;
        // If count is odd and no center character has been added yet, add one extra
        if (count % 2 == 1 && !centerAdded) {
            palindromeLength++;
            centerAdded = true;
        }
    }

    return palindromeLength;
}

int main() {
    string s = "abcccd";
    cout << longestPalindrome(s) << endl;
    return 0;
}
```

Gas Station

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Greedy](#)

Lists: Grind 169

Problem:

There are n gas stations along a circular route, where the amount of gas at the i th station is $gas[i]$.

You have a car with an unlimited gas tank and it costs $cost[i]$ of gas to travel from the i th station to its next $(i + 1)$ th station. You begin the journey with an empty tank at one of the gas stations.

Given two integer arrays gas and $cost$, return the starting gas station's index if you can travel around the circuit once in the clockwise direction, otherwise return -1 . If there exists a solution, it is guaranteed to be unique.

Example 1:

Input: gas = [1,2,3,4,5], cost = [3,4,5,1,2]

Output: 3

Explanation:

Start at station 3 (index 3) and fill up with 4 unit of gas. Your tank = $0 + 4 = 4$

Travel to station 4. Your tank = $4 - 1 + 5 = 8$

Travel to station 0. Your tank = $8 - 2 + 1 = 7$

Travel to station 1. Your tank = $7 - 3 + 2 = 6$

Travel to station 2. Your tank = $6 - 4 + 3 = 5$

Travel to station 3. The cost is 5. Your gas is just enough to travel back to station 3.

Therefore, return 3 as the starting index.

Example 2:

Input: gas = [2,3,4], cost = [3,4,3]

Output: -1

Explanation:

You can't start at station 0 or 1, as there is not enough gas to travel to the next station.

Let's start at station 2 and fill up with 4 unit of gas. Your tank = $0 + 4 = 4$

Travel to station 0. Your tank = $4 - 3 + 2 = 3$

Travel to station 1. Your tank = $3 - 3 + 3 = 3$

You cannot travel back to station 2, as it requires 4 unit of gas but you only have 3.

Therefore, you can't travel around the circuit once no matter where you start.

Constraints:

- $n == \text{gas.length} == \text{cost.length}$
- $1 \leq n \leq 105$
- $0 \leq \text{gas}[i], \text{cost}[i] \leq 104$
- The input is generated such that the answer is unique.

[*] Greedy — Pattern Solution (stored optimal)

Python

```

# Define a function to find starting gas station index
def canCompleteCircuit(gas, cost):
    total_surplus = 0 # Total gas surplus after completing the route
    current_surplus = 0 # Gas surplus while iterating from a candidate start station
    start_index = 0 # Candidate starting station index

    # Loop through each station
    for i in range(len(gas)):
        # Calculate net gas after leaving station i
        surplus = gas[i] - cost[i]
        total_surplus += surplus
        current_surplus += surplus

        # If current surplus becomes negative, station i is not a valid start.
        if current_surplus < 0:
            # Reset starting station to the next station
            start_index = i + 1
            current_surplus = 0 # Reset current surplus

    # Check if overall surplus is non-negative
    return start_index if total_surplus >= 0 else -1

# Example usage:
gas = [1,2,3,4,5]
cost = [3,4,5,1,2]
print(canCompleteCircuit(gas, cost)) # Output: 3

```

C++

```

// C++ solution using the greedy approach
#include <vector>
using namespace std;

class Solution {
public:
    int canCompleteCircuit(vector<int>& gas, vector<int>& cost) {
        int totalSurplus = 0; // Total surplus across all stations
        int currentSurplus = 0; // Surplus from the candidate station
        int startIndex = 0; // Candidate starting station index

        // Iterate through gas stations
        for (int i = 0; i < gas.size(); i++) {
            int surplus = gas[i] - cost[i]; // Compute surplus at station i
            totalSurplus += surplus;
            currentSurplus += surplus;

            // If current surplus falls negative, update candidate starting station index
            if (currentSurplus < 0) {
                startIndex = i + 1;
                currentSurplus = 0; // Reset for next candidate segment
            }
        }

        // If the total surplus is non-negative, return startIndex otherwise -1
    }
}

```

```

        return totalSurplus >= 0 ? startIndex : -1;
    }
};

// Sample usage:
// int main() {
//     vector<int> gas = {1,2,3,4,5};
//     vector<int> cost = {3,4,5,1,2};
//     Solution sol;
//     cout << sol.canCompleteCircuit(gas, cost); // Should output 3
//     return 0;
// }

MEDIUM

Largest Number

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [String](#) · [Greedy](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given a list of non-negative integers `nums`, arrange them such that they form the largest number and return it.

Since the result may be very large, so you need to return a string instead of an integer.

Example 1:

Input: `nums = [10,2]`

Output: `"210"`

Example 2:

Input: `nums = [3,30,34,5,9]`

Output: `"9534330"`

Constraints:

- $1 \leq \text{nums.length} \leq 100$
- $0 \leq \text{nums}[i] \leq 10^9$

MEDIUM

Wiggle Sort

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Greedy](#) · [Sorting](#)

Lists: Premium 98

Problem:

Given an integer array `nums`, reorder it such that `nums[0] <= nums[1] >= nums[2] <= nums[3]....`

You may assume the input array always has a valid answer.

Example 1:

Input: `nums = [3,5,2,1,6,4]`

Output: `[3,5,1,6,2,4]`

Explanation: `[1,6,2,5,3,4]` is also accepted.

Example 2:

Input: `nums = [6,6,5,6,3,8]`

Output: `[6,6,5,6,3,8]`

Constraints:

- $1 \leq \text{nums.length} \leq 5 \times 10^4$
- $0 \leq \text{nums}[i] \leq 10^4$
- It is guaranteed that there will be an answer for the given input `nums`.

Follow up: Could you solve the problem in $O(n)$ time complexity?

                nums[i], nums[i - 1] = nums[i - 1], nums[i]
```

Python

```

'''
math prove:

example [3, 5, 2, 1]
when reaching 2, all good
then next, is 1,
so here comes the question, will the number after 2 violating the wiggle rule?
answer is no.

in example, when reaching 2:
* if [3, 5, 2, 10], so 10 is bigger than 2, then no swap needed according to the if () conditions

* if [3, 5, 2, 1], so previous round, guaranteed that 2 is smaller than 5.
  And, now a swap needed meaning the number is smaller than 2, i.e. must be smaller than 5, so wiggle
  rule is still good

[*] Greedy — Pattern Solution (matched from community answers)

Python

```

'''
math prove:

example [3, 5, 2, 1]
when reaching 2, all good
then next, is 1,
so here comes the question, will the number after 2 violating the wiggle rule?
answer is no.

in example, when reaching 2:
* if [3, 5, 2, 10], so 10 is bigger than 2, then no swap needed according to the if () conditions

* if [3, 5, 2, 1], so previous round, guaranteed that 2 is smaller than 5.
  And, now a swap needed meaning the number is smaller than 2, i.e. must be smaller than 5, so wiggle
  rule is still good

MEDIUM

Array of Doubled Pairs

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Greedy](#) · [Sorting](#)

Lists: [CodeSignal](#)

Problem:

Given an integer array of even length arr, return true if it is possible to reorder arr such that $arr[2 * i + 1] = 2 * arr[2 * i]$ for every $0 \leq i < \text{len}(arr) / 2$, or false otherwise.

Example 1:

Input: arr = [3,1,3,6]

Output: false

Example 2:

Input: arr = [2,1,2,6]

Output: false

Example 3:

Input: arr = [4,-2,2,-4]

Output: true

Explanation: We can take two groups, $[-2, -4]$ and $[2, 4]$ to form $[-2, -4, 2, 4]$ or $[2, 4, -2, -4]$.

Constraints:

- $2 \leq \text{arr.length} \leq 3 \times 10^4$
- arr.length is even.
- $-105 \leq \text{arr}[i] \leq 105$

Longest Palindrome by Concatenating Two Letter Words

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [String](#) · [Greedy](#) · [Counting](#)

Lists: [CodeSignal](#)

Problem:

You are given an array of strings `words`. Each element of `words` consists of two lowercase English letters.

Create the longest possible palindrome by selecting some elements from `words` and concatenating them in any order. Each element can be selected at most once.

Return the length of the longest palindrome that you can create. If it is impossible to create any palindrome, return 0.

A palindrome is a string that reads the same forward and backward.

Example 1:

Input: `words = ["lc","cl","gg"]`

Output: 6

Explanation: One longest palindrome is "lc" + "gg" + "cl" = "lcggcl", of length 6.

Note that "clggcl" is another longest palindrome that can be created.

Example 2:

Input: `words = ["ab","ty","yt","lc","cl","ab"]`

Output: 8

Explanation: One longest palindrome is "ty" + "lc" + "cl" + "yt" = "tylcclyt", of length 8.

Note that "lcyttycl" is another longest palindrome that can be created.

Example 3:

Input: `words = ["cc","ll","xx"]`

Output: 2

Explanation: One longest palindrome is "cc", of length 2.

Note that "ll" is another longest palindrome that can be created, and so is "xx".

Constraints:

- $1 \leq \text{words.length} \leq 105$
- `words[i].length == 2`
- `words[i]` consists of lowercase English letters.

Python

```
# Brute Force Approach
class Solution:
    def longestPalindrome(self, words):
        # Brute Force  $O(n^2)$  - check all subsets/orderings exhaustively
        from itertools import permutations
        best = float('inf')
        for perm in permutations(words):
            cost = sum(perm)
            best = min(best, cost)
        return best
```

Python

Python

```
# Python solution
from collections import Counter

class Solution:
    def longestPalindrome(self, words):
        # Count the frequency of each word
        word_count = Counter(words)
        length = 0 # Total words used count (each adds 2 letters)
        center_used = False

        for word, count in list(word_count.items()):
            reverse = word[::-1] # Get the reverse of the current word

            if word == reverse:
                # For words that are palindromic themselves (e.g. "gg")
                pairs = count // 2
                length += pairs * 2 # Each pair adds 2 words (4 letters)
                # If an extra word exists and center is not used, add one word in the center
                if count % 2 == 1 and not center_used:
                    length += 1
                    center_used = True
            else:
                # For words that are not self-palindromic.
                if reverse in word_count:
                    # We only count each pair once, so use minimum and then set the reverse count to 0.

                    pair_count = min(count, word_count[reverse])
                    length += pair_count * 2 # each pair contributes two words
                    # Set reverse count to 0 to avoid double counting later.
                    word_count[reverse] = 0

        return length * 2 # Each word is of length 2

# Example usage:
# sol = Solution()
# print(sol.longestPalindrome(["lc", "cl", "gg"])) # Output: 6

[*] Greedy — Pattern Solution (stored optimal)

Python

```
# Python solution
from collections import Counter

class Solution:
    def longestPalindrome(self, words):
        # Count the frequency of each word
        word_count = Counter(words)
        length = 0 # Total words used count (each adds 2 letters)
        center_used = False

        for word, count in list(word_count.items()):
            reverse = word[::-1] # Get the reverse of the current word

            if word == reverse:
                # For words that are palindromic themselves (e.g. "gg")
                pairs = count // 2
                length += pairs * 2 # Each pair adds 2 words (4 letters)
                # If an extra word exists and center is not used, add one word in the center
                if count % 2 == 1 and not center_used:
                    length += 1
                    center_used = True
            else:
                # For words that are not self-palindromic.
                if reverse in word_count:
                    # We only count each pair once, so use minimum and then set the reverse count to 0.
```

```

        pair_count = min(count, word_count[reverse])
        length += pair_count * 2 # each pair contributes two words
        # Set reverse count to 0 to avoid double counting later.
        word_count[reverse] = 0
    return length * 2 # Each word is of length 2

# Example usage:
# sol = Solution()
# print(sol.longestPalindrome(["lc", "cl", "gg"])) # Output: 6

```

C++

```

// C++ solution
#include <vector>
#include <string>
#include <unordered_map>
#include <algorithm>
using namespace std;

class Solution {
public:
    int longestPalindrome(vector<string>& words) {
        unordered_map<string, int> wordCount;
        for (const auto& word : words) {
            wordCount[word]++;
        }
        int length = 0;
        bool centerUsed = false;

        for (auto& [word, count] : wordCount) {
            string reverse = word;
            reverse[0] = word[1];
            reverse[1] = word[0];

            if (word == reverse) {
                // Self-palindromic word
                length += (count / 2) * 2;
            }
        }
        if (!centerUsed) {
            // If there is a word that is its own reverse, we can use it as the center
            for (auto& [word, count] : wordCount) {
                if (word[0] == word[1]) {

}
};

// Example usage:
// int main() {
//     Solution sol;
//     vector<string> words = {"lc", "cl", "gg"};
//     int result = sol.longestPalindrome(words); // result should be 6
//     return 0;
// }

```

Quick Review — Greedy 6 questions · insights · complexity · solution

#409 Longest Palindrome [Easy]

Key Insights

- Count the frequency of each character.
- For each character, you can use pairs (even count or odd count minus one) to form the palindrome.
- If any character has an odd frequency, you can add one extra character as the center of the palindrome.

Space & Time

Time Complexity: $O(n)$, where n is the length of the string.

Space Complexity: $O(1)$ since the frequency counter will have at most 52 keys (considering both uppercase and lowercase letters).

Solution

The solution uses a hash table to count the frequency of each character. For every character, the maximum number of characters that can be used in a palindrome is determined by taking the largest even number that is less than or equal to its frequency (which is $\text{frequency} - (\text{frequency} \% 2)$). If there exists any character with an odd frequency, one of these can be used as the center of the palindrome, adding an extra character to the total length. This greedy approach efficiently computes the length of the largest possible palindrome from the available characters.

#134 Gas Station [Medium]

Key Insights

- If the total amount of gas available is less than the total travel cost, then completing the circuit is impossible.
- A greedy approach can be used by keeping track of the current surplus of gas. If the surplus becomes negative at any station, the journey cannot start from any station before that point.
- Restart the journey from the next station whenever the surplus goes negative.
- The problem guarantees that if a solution exists, it is unique.

Space & Time

Time Complexity: $O(n)$, where n is the number of gas stations, as we traverse the list only once.

Space Complexity: $O(1)$, as no extra space is used other than a few variables.

Solution

The solution involves iterating over the list of stations while maintaining two variables: one for the current gas surplus and one for the total gas surplus. If at any station the current surplus drops below zero, the current starting station is not viable and we set the starting station to the next index and reset the current surplus. After one pass, if the total gas surplus is non-negative, then the identified station is the valid starting point.

#179 Largest Number [Medium]

Key Insights

- The order in which numbers appear drastically affects the concatenated result.
- A custom sorting strategy is required where two numbers are compared by checking which concatenation (first-second vs second-first) yields a larger number.
- Edge case: When the numbers are all zeros, the result should be "0" instead of several leading zeros.

Space & Time

Time Complexity: $O(n \log n * k)$, where n is the number of elements in the array and k is the maximum number of digits in a number (due to string comparisons in the custom sort).

Space Complexity: $O(n * k)$ for storing and processing the strings.

Solution

We solve the problem by converting all integers to strings so that we can use string concatenation to compare the results. A custom comparator is defined that, given two number strings, compares the concatenated results in both orders. By sorting the array using this comparator in descending order, we ensure that placing the highest contributing number first yields the largest possible number. After sorting, a check is performed to return "0" if the highest number is "0". Finally, the sorted strings are concatenated to form the answer.

#280 Wiggle Sort [Medium]

Key Insights

- The alternating "wiggle" requirement can be satisfied by ensuring two conditions:
- For every odd index i , $\text{nums}[i]$ should be greater than or equal to $\text{nums}[i-1]$.
- For every even index i (where $i > 0$), $\text{nums}[i]$ should be less than or equal to $\text{nums}[i-1]$.
- A single pass through the array can ensure these conditions by swapping adjacent elements when the condition is violated.
- This greedy approach works because the local adjustments guarantee the overall wiggle pattern without needing to sort the entire array.

Space & Time

Time Complexity: $O(n)$ — Only one pass through the array is needed.

Space Complexity: $O(1)$ — The modifications are done in-place without extra data structures.

Solution

We can achieve a wiggle sort in one pass by iterating through the array and, at each index i (starting from 1), checking if the pair $(\text{nums}[i-1], \text{nums}[i])$ satisfies the wiggle condition. If i is odd, $\text{nums}[i]$ should be at least $\text{nums}[i-1]$; if not, we swap them. Conversely, if i is even and $\text{nums}[i]$ is greater than $\text{nums}[i-1]$, then we swap them. These local swaps adjust the order incrementally while ensuring that the overall wiggle pattern is maintained. This greedy approach works because only two adjacent numbers are involved in any violation and fixing them locally does not disturb the rest of the order.

#954 Array of Doubled Pairs [Medium]

Key Insights

- Sort the array based on the absolute value of the elements to handle negative numbers correctly.
- Use a hash table (or frequency counter) to track the occurrence of each element.
- For each number in the sorted list, if the number is still available in the frequency map, try to pair it with its double.
- Decrement the appropriate counts and validate that it is possible to find sufficient doubles for all numbers.
- Special case: when dealing with zeros, pairing works within the same value.

Space & Time

Time Complexity: $O(n \log n)$ due to sorting.

Space Complexity: $O(n)$ for storing the frequency map.

Solution

The solution starts by counting the frequency of each element in the array. Sorting the array by absolute value ensures that when we process an element, any potential pair (i.e., its double) comes later in the sequence. For each number, if there are available occurrences, we try to match it with its double. If there are not enough doubles available, the answer is false. If all elements can be paired appropriately by decrementing their counts in the frequency map, the function returns true.

#2131 Longest Palindrome by Concatenating Two Letter Words [Medium]

Key Insights

- Pair words with their reverse (e.g., "ab" with "ba") to form a palindrome.

- Handle words that are palindromic by themselves (like "gg" or "aa") differently; they can be used in pairs and one extra can be placed in the center.
- Use a hash map (or dictionary) to count frequencies of each word.
- For non-palindromic word pairs, consider each pair only once to avoid double counting.
- For self-palindromic words, count how many pairs can be used and whether an extra word can be placed in the middle to maximize length.

Space & Time

Time Complexity: $O(n)$, where n is the number of words, since we iterate through the list and perform constant time operations per word.

Space Complexity: $O(n)$, to store counts of words in the hash map.

Solution

The approach is to count the occurrences of each word using a hash map. For each word:

– If the word is not self-palindromic, check if its reverse exists and form pairs by considering the minimum count between the word and its reverse. – If the word is self-palindromic, form as many pairs as possible (using $\text{count} // 2$) and note if there is any word left; you can use one extra self-palindromic word as the center of the palindrome. Finally, compute the total length by multiplying the number of words used by 2, since each word contributes 2 characters.

MEDIUM

Debounce

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

JavaScript

Lists: Premium 98

Problem:

Given a function `fn` and a time in milliseconds `t`, return a debounced version of that function.

A debounced function is a function whose execution is delayed by `t` milliseconds and whose execution is cancelled if it is called again within that window of time. The debounced function should also receive the passed parameters.

For example, let's say `t = 50ms`, and the function was called at 30ms, 60ms, and 100ms.

The first 2 function calls would be cancelled, and the 3rd function call would be executed at 150ms.

If instead `t = 35ms`, The 1st call would be cancelled, the 2nd would be executed at 95ms, and the 3rd would be executed at 135ms.

The above diagram shows how debounce will transform events. Each rectangle represents 100ms and the debounce time is 400ms. Each color represents a different set of inputs.

Please solve it without using lodash's `_debounce()` function.

Example 1:

Input:

`t = 50`

```
calls = [
  {"t": 50, inputs: [1]},
  {"t": 75, inputs: [2]}
]
```

Output: `[{"t": 125, inputs: [2]}`

Explanation:

```
let start = Date.now();
function log(...inputs) {
  console.log([Date.now() - start, inputs ])
}
const dlog = debounce(log, 50);
setTimeout(() => dlog(1), 50);
setTimeout(() => dlog(2), 75);
```

The 1st call is cancelled by the 2nd call because the 2nd call occurred before 100ms

The 2nd call is delayed by 50ms and executed at 125ms. The inputs were (2).

Example 2:

Input:

`t = 20`

```
calls = [
```

```

    {"t": 50, inputs: [1]},
    {"t": 100, inputs: [2]}
  ]
Output: [{"t": 70, inputs: [1]}, {"t": 120, inputs: [2]}]
Explanation:
The 1st call is delayed until 70ms. The inputs were (1).
The 2nd call is delayed until 120ms. The inputs were (2).

```

Example 3:

```

Input:
t = 150
calls = [
  {"t": 50, inputs: [1, 2]},
  {"t": 300, inputs: [3, 4]},
  {"t": 300, inputs: [5, 6]}
]
Output: [{"t": 200, inputs: [1,2]}, {"t": 450, inputs: [5, 6]}]
Explanation:
The 1st call is delayed by 150ms and ran at 200ms. The inputs were (1, 2).
The 2nd call is cancelled by the 3rd call
The 3rd call is delayed by 150ms and ran at 450ms. The inputs were (5, 6).

```

Constraints:

- $0 \leq t \leq 1000$
- $1 \leq \text{calls.length} \leq 10$
- $0 \leq \text{calls}[i].t \leq 1000$
- $0 \leq \text{calls}[i].\text{inputs.length} \leq 10$

TypeScript

TypeScript

```

type F = (...args: number[]) => void;

function debounce(fn: F, t: number): F {
  let timeout: ReturnType<typeof setTimeout> | undefined;
  return function (...args) {
    clearTimeout(timeout);
    timeout = setTimeout(() => fn(...args), t);
  };
}

```

TypeScript

```

type F = (...p: any[]) => any;

function debounce(fn: F, t: number): F {
    let timeout: ReturnType<typeof setTimeout> | undefined;

    return function (...args) {
        if (timeout !== undefined) {
            clearTimeout(timeout);
        }
        timeout = setTimeout(() => {
            fn.apply(this, args);
        }, t);
    };
}

/**
 * const log = debounce(console.log, 100);
 * log('Hello'); // cancelled
 * log('Hello'); // cancelled
 * log('Hello'); // Logged at t=100ms
 */

```

TypeScript

```

type F = (...p: any[]) => any;

function debounce(fn: F, t: number): F {
    let timeout: ReturnType<typeof setTimeout> | undefined;

    return function (...args) {
        if (timeout !== undefined) {
            clearTimeout(timeout);
        }
        timeout = setTimeout(() => {
            fn.apply(this, args);
        }, t);
    };
}

/**

JSON Deep Equal

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

JavaScript

Lists: Premium 98

Problem:

Given two values o1 and o2, return a boolean value indicating whether two values, o1 and o2, are deeply equal.

For two values to be deeply equal, the following conditions must be met:

- If both values are primitive types, they are deeply equal if they pass the === equality check.
- If both values are arrays, they are deeply equal if they have the same elements in the same order, and each element is also deeply equal according to these conditions.
- If both values are objects, they are deeply equal if they have the same keys, and the associated values for each key are also deeply equal according to these conditions.

You may assume both values are the output of JSON.parse. In other words, they are valid JSON.

Please solve it without using lodash's _isEqual() function

Example 1:

Input: o1 = {"x":1,"y":2}, o2 = {"x":1,"y":2}
 Output: true
 Explanation: The keys and values match exactly.

Example 2:

Input: o1 = {"y":2,"x":1}, o2 = {"x":1,"y":2}
 Output: true
 Explanation: Although the keys are in a different order, they still match exactly.

Example 3:

Input: o1 = {"x":null,"L":[1,2,3]}, o2 = {"x":null,"L":["1","2","3"]}

Output: false

Explanation: The array of numbers is different from the array of strings.

Example 4:

Input: o1 = true, o2 = false

Output: false

Explanation: true !== false

Constraints:

- $1 \leq \text{JSON.stringify(o1).length} \leq 105$
- $1 \leq \text{JSON.stringify(o2).length} \leq 105$
- $\text{maxNestingDepth} \leq 1000$

TypeScript

TypeScript

```
type JSONValue =
  | null
  | boolean
  | number
  | string
  | JSONValue[]
  | { [key: string]: JSONValue };

function areDeeplyEqual(o1: JSONValue, o2: JSONValue): boolean {
  if (o1 === o2) {
    return true;
  }
  if (o1 === null || o1 === undefined || o2 === null || o2 === undefined) {
    return false;
  }
  if (typeof o1 !== 'object' || typeof o2 !== 'object') {
    return false;
  }
  if (Array.isArray(o1) !== Array.isArray(o2)) {
    return false;
  }
  if (Object.keys(o1).length !== Object.keys(o2).length) {
    return false;
  }
  for (const key in o1) {
    if (!areDeeplyEqual(o1[key], o2[key])) {
      return false;
    }
  }
  return true;
}
```

Python

Python

```
def deep_equal(o1, o2):
    # If both are exactly equal, return True
    if o1 == o2:
        return True
    # If types differ, they are not equal
    if type(o1) != type(o2):
        return False
    # If both are lists, check length and recursively compare each element
    if isinstance(o1, list):
        if len(o1) != len(o2):
            return False
        for item1, item2 in zip(o1, o2):
            if not deep_equal(item1, item2):
                return False
        return True
    # If both are dictionaries, check that they have the same keys and values
    if isinstance(o1, dict):
        if set(o1.keys()) != set(o2.keys()):
            return False
        for key in o1:
            if not deep_equal(o1[key], o2[key]):
                return False
        return True
    # Fallback for other types (should not reach here for valid JSON)
    return False
```

```
# Example usage:
# print(deep_equal({"x": 1, "y": 2}, {"y": 2, "x": 1}))
```

[*] JavaScript — Pattern Solution (stored optimal)

Python

```
def deep_equal(o1, o2):
    # If both are exactly equal, return True
    if o1 == o2:
        return True
    # If types differ, they are not equal
    if type(o1) != type(o2):
        return False
    # If both are lists, check length and recursively compare each element
    if isinstance(o1, list):
        if len(o1) != len(o2):
            return False
        for item1, item2 in zip(o1, o2):
            if not deep_equal(item1, item2):
                return False
        return True
    # If both are dictionaries, check that they have the same keys and values
    if isinstance(o1, dict):
        if set(o1.keys()) != set(o2.keys()):
            return False
        for key in o1:
            if not deep_equal(o1[key], o2[key]):
                return False
        return True
    # Fallback for other types (should not reach here for valid JSON)
    return False
```

```
# Example usage:
# print(deep_equal({"x": 1, "y": 2}, {"y": 2, "x": 1}))
```

C++

```
// Note: This C++ solution assumes the use of the nlohmann::json library.
// Include the library header and use the nlohmann::json type.
#include <iostream>
#include <nlohmann/json.hpp>
#include <vector>
#include <string>
#include <cassert>
using json = nlohmann::json;

// Recursive function to compare two json objects deeply.
bool deepEqual(const json &o1, const json &o2) {
    // If both are exactly equal, return true.
    if (o1 == o2) return true;

    // If types differ, return false.
    if (o1.type() != o2.type()) return false;

    // If both are arrays, check size and compare each element.
    if (o1.is_array()) {
        if (o1.size() != o2.size()) return false;
        for (size_t i = 0; i < o1.size(); ++i) {
            if (!deepEqual(o1[i], o2[i])) return false;
        }
        return true;
    }

    // If both are objects, compare keys and then each key-value pair.
    if (o1.is_object()) {
        if (o1.size() != o2.size()) return false;
        for (auto it = o1.begin(); it != o1.end(); ++it) {
            std::string key = it.key();
            // Check if the second object contains the key.
            if (o2.find(key) == o2.end()) return false;
            if (!deepEqual(it.value(), o2[key])) return false;
        }
        return true;
    }

    // For number, string, boolean, or null, the operator== check suffices.
    return o1 == o2;
}

int main() {
    // Example usage:
    json obj1 = {"x", 1}, {"y", 2};
    json obj2 = {"y", 2}, {"x", 1};
    assert(deepEqual(obj1, obj2) == true);
    std::cout << "Test passed!" << std::endl;
    return 0;
}
```

MEDIUM

Memoize

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[JavaScript](#)

Lists: Premium 98

Problem:

Given a function `fn`, return a memoized version of that function.

A memoized function is a function that will never be called twice with the same inputs. Instead it will return a cached value.

`fn` can be any function and there are no constraints on what type of values it accepts. Inputs are considered identical if they are `===` to each other.

Example 1:

Input:

```
getInputs = () => [[2,2],[2,2],[1,2]]
```

```
fn = function (a, b) { return a + b; }
```

Output: `[{"val":4,"calls":1},{ "val":4,"calls":1},{ "val":3,"calls":2}]`

Explanation:

```
const inputs = getInputs();
const memoized = memoize(fn);
for (const arr of inputs) {
  memoized(...arr);
}
```

For the inputs of (2, 2): $2 + 2 = 4$, and it required a call to `fn()`.

For the inputs of (2, 2): $2 + 2 = 4$, but those inputs were seen before so no call to `fn()` was required.

For the inputs of (1, 2): $1 + 2 = 3$, and it required another call to `fn()` for a total of 2.

Example 2:

Input:

```
getInputs = () => [{},{},[{}],[{}],[{}],[{}]]
```

```
fn = function (a, b) { return ({...a, ...b}); }
```

Output: `[{"val":{},"calls":1},{ "val":{},"calls":2},{ "val":{},"calls":3}]`

Explanation:

Merging two empty objects will always result in an empty object. It may seem like there should only be 1 call to `fn()` because of cache-hits, however none of those objects are `===` to each other.

Example 3:

Input:

```
getInputs = () => { const o = {}; return [[o,o],[o,o],[o,o]]; }
```

```
fn = function (a, b) { return ({...a, ...b}); }
```

Output: `[{"val":{},"calls":1},{ "val":{},"calls":1},{ "val":{},"calls":1}]`

Explanation:

Merging two empty objects will always result in an empty object. The 2nd and 3rd third function calls result in a cache-hit. This is because every object passed in is identical.

Constraints:

- `1 <= inputs.length <= 105`
- `0 <= inputs.flat().length <= 105`
- `inputs[i][j] != NaN`

TypeScript

TypeScript

```
type Fn = (...params: any) => any;

function memoize(fn: Fn): Fn {
  const idxMap: Map<string, number> = new Map();
  const cache: Map<string, any> = new Map();

  const getIdx = (obj: any): number => {
    if (!idxMap.has(obj)) {
      idxMap.set(obj, idxMap.size);
    }
    return idxMap.get(obj)!;
  };

  return function (...params: any) {
    const key = params.map(getIdx).join(',');
    if (!cache.has(key)) {
      cache.set(key, fn(...params));
    }
    return cache.get(key)!;
  };
}

/**
 * let callCount = 0;
 * const memoizedFn = memoize(function (a, b) {
 *
 * callCount += 1;
 * return a + b;
 * })
 * memoizedFn(2, 3) // 5
 * memoizedFn(2, 3) // 5
 * console.log(callCount) // 1
 */
```

TypeScript

```

type Fn = (...params: any) => any;

function memoize(fn: Fn): Fn {
  const idxMap: Map<string, number> = new Map();
  const cache: Map<string, any> = new Map();

  const getIdx = (obj: any): number => {
    if (!idxMap.has(obj)) {
      idxMap.set(obj, idxMap.size);
    }
    return idxMap.get(obj)!;
  };

  return function (...params: any) {
    const key = params.map(getIdx).join(',');
    if (!cache.has(key)) {
      cache.set(key, fn(...params));
    }
    return cache.get(key)!;
  };
}

/**
 * let callCount = 0;
 * const memoizedFn = memoize(function (a, b) {
 *
 *   callCount += 1;
 *   return a + b;
 * })
 * memoizedFn(2, 3) // 5
 * memoizedFn(2, 3) // 5
 * console.log(callCount) // 1
 */

```

Python

Python

```

# Define a function 'memoize' that takes a function 'fn' and returns a memoized version.
def memoize(fn):
    cache = {} # Dictionary to cache computed values
    call_count = 0 # Counter for real function calls

    # The wrapper function handles any number of arguments.
    def wrapper(*args):
        nonlocal call_count
        # Use the arguments tuple as a key (order sensitive).
        if args not in cache:
            call_count += 1 # Increment call count when computing new result
            cache[args] = fn(*args)
        return cache[args]

    # Expose the getCallCount method on the memoized function.
    wrapper.getCallCount = lambda: call_count
    return wrapper

# Example usage:
# def sum_func(a, b): return a + b
# memoizedSum = memoize(sum_func)
# print(memoizedSum(2, 2))
# print(memoizedSum(2, 2))
# print(memoizedSum.getCallCount())

```

[*] JavaScript — Pattern Solution (stored optimal)

Python

```

# Define a function 'memoize' that takes a function 'fn' and returns a memoized version.
def memoize(fn):
    cache = {} # Dictionary to cache computed values
    call_count = 0 # Counter for real function calls

    # The wrapper function handles any number of arguments.
    def wrapper(*args):
        nonlocal call_count
        # Use the arguments tuple as a key (order sensitive).
        if args not in cache:
            call_count += 1 # Increment call count when computing new result
            cache[args] = fn(*args)
        return cache[args]

    # Expose the getCallCount method on the memoized function.
    wrapper.getCallCount = lambda: call_count
    return wrapper

# Example usage:
# def sum_func(a, b): return a + b
# memoizedSum = memoize(sum_func)
# print(memoizedSum(2, 2))
# print(memoizedSum(2, 2))
# print(memoizedSum.getCallCount())

```

C++

```
// C++ solution using variadic templates and tuple as the cache key.
// Note: This solution assumes that the function parameters can be stored in a tuple and hashed.
// A helper struct to combine hashes for tuple elements is used.
```

```
#include <functional>
#include <tuple>
#include <unordered_map>
#include <iostream>

// Helper to hash a tuple (C++11 and later)
namespace std {
    template <class T>
    inline void hash_combine(std::size_t & seed, const T & v) {
        seed ^= std::hash<T>()(v) + 0x9e3779b9 + (seed << 6) + (seed >> 2);
    }

    template <typename Tuple, size_t Index = std::tuple_size<Tuple>::value - 1>
    struct TupleHashImpl {
        static void apply(std::size_t & seed, const Tuple & tuple) {
            TupleHashImpl<Tuple, Index-1>::apply(seed, tuple);
            hash_combine(seed, std::get<Index>(tuple));
        }
    };

    template <typename Tuple>
```

```
    struct TupleHashImpl<Tuple, 0> {
        static void apply(std::size_t & seed, const Tuple & tuple) {
            hash_combine(seed, std::get<0>(tuple));
        }
    };

    template <typename ... TT>
    struct hash<std::tuple<TT...>> {
        size_t operator()(const std::tuple<TT...>& tt) const {
            size_t seed = 0;
            TupleHashImpl<std::tuple<TT...> >::apply(seed, tt);
            return seed;
        }
    };
}
```

```
// Generic Memoize class using a lambda function.
template <typename Func, typename Ret, typename... Args>
class Memoize {
public:
    // Constructor takes in the function to memoize.
    Memoize(Func f) : fn(f), callCount(0) {}

    // Overloading operator() to make the class callable.
    Ret operator()(Args... args) {
```

```

        auto key = std::make_tuple(args...); // Create key with the given arguments.
        if (cache.find(key) == cache.end()) {
            callCount++;
            cache[key] = fn(args...);
        }
        return cache[key];
    }

    // Method to get the call count.
    int getCallCount() const {
        return callCount;
    }

private:
    Func fn;
    int callCount;
    std::unordered_map<std::tuple<Args...>, Ret> cache; // Cache mapping argument tuple to result.
};

// Helper function to create a Memoize instance.
template <typename Func, typename Ret, typename... Args>
auto memoize(Func f) {
    return Memoize<Func, Ret, Args...>(f);
}

// Example usage:
// int sum(int a, int b) { return a + b; }
// int main() {
//     auto memoizedSum = memoize<decltype(sum), int, int, int>(sum);
//     std::cout << memoizedSum(2, 2) << std::endl;

```

MEDIUM

Convert Object to JSON String

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

JavaScript

Lists: Premium 98

Problem:

Given a value, return a valid JSON string of that value. The value can be a string, number, array, object, boolean, or null. The returned string should not include extra spaces. The order of keys should be the same as the order returned by `Object.keys()`.

Please solve it without using the built-in `JSON.stringify` method.

Example 1:

Input: object = {"y":1,"x":2}

Output: {"y":1,"x":2}

Explanation:

Return the JSON representation.

Note that the order of keys should be the same as the order returned by `Object.keys()`.

Example 2:

Input: object = {"a":"str","b":-12,"c":true,"d":null}

Output: {"a":"str","b":-12,"c":true,"d":null}

Explanation:

The primitives of JSON are strings, numbers, booleans, and null.

Example 3:

Input: object = {"key":{"a":1,"b":[{},null,"Hello"]}}

Output: {"key":{"a":1,"b":[{},null,"Hello"]}}

Explanation:

Objects and arrays can include other objects and arrays.

Example 4:

Input: object = true

Output: true

Explanation:

Primitive types are valid inputs.

Constraints:

- value is a valid JSON value
- $1 \leq \text{JSON.stringify(object).length} \leq 105$
- $\text{maxNestingLevel} \leq 1000$
- all strings contain only alphanumeric characters

TypeScript

TypeScript

```
type JSONValue =
  | null
  | boolean
  | number
  | string
  | JSONValue[]
  | { [key: string]: JSONValue };

function jsonStringify(object: JSONValue): string {
  if (object === null) {
    return 'null';
  }
  if (typeof object === 'boolean' || typeof object === 'number') {
    return String(object);
  }
  if (typeof object === 'string') {
    return `"${object}"`;
  }
  if (Array.isArray(object)) {
    const elems = object.map((elem) => jsonStringify(elem));
    return `[${elems.join(',')}]`;
  }
  const pairs = Object.keys(object).map(
    (key) => `"${key}":${jsonStringify(object[key])}`
  );
  return `{${pairs.join(',')}`;
}
```

Python

Python

```
def myStringify(value):
    # If value is None, return "null"
    if value is None:
        return "null"
    # If value is a boolean, convert to "true" or "false"
    if isinstance(value, bool):
        return "true" if value else "false"
    # If value is a number, return its string representation
    if isinstance(value, (int, float)):
        return str(value)
    # If value is a string, enclose it in double quotes
    if isinstance(value, str):
        return '"' + value + '"'
    # If value is a list, recursively process its elements
    if isinstance(value, list):
        return '[' + ','.join(myStringify(item) for item in value) + ']'
    # If value is a dictionary, iterate keys in the order of insertion
    if isinstance(value, dict):
        items = []
        for key in value:
            items.append('"' + key + '":' + myStringify(value[key]))
        return '{' + ','.join(items) + '}'
    # Fallback (should not be reached with valid JSON types)
    return ""

# Example usage:
test_obj = {"y": 1, "x": 2}
print(myStringify(test_obj))
```

[*] JavaScript — Pattern Solution (stored optimal)

Python

```
def myStringify(value):
    # If value is None, return "null"
    if value is None:
        return "null"
    # If value is a boolean, convert to "true" or "false"
    if isinstance(value, bool):
        return "true" if value else "false"
    # If value is a number, return its string representation
    if isinstance(value, (int, float)):
        return str(value)
    # If value is a string, enclose it in double quotes
    if isinstance(value, str):
        return '"' + value + '"'
    # If value is a list, recursively process its elements
    if isinstance(value, list):
        return '[' + ','.join(myStringify(item) for item in value) + ']'
    # If value is a dictionary, iterate keys in the order of insertion
    if isinstance(value, dict):
        items = []
        for key in value:
            items.append('"' + key + '"' + ':' + myStringify(value[key]))
        return '{' + ','.join(items) + '}'
    # Fallback (should not be reached with valid JSON types)
    return ""

# Example usage:
test_obj = {"y": 1, "x": 2}
print(myStringify(test_obj))
```

C++

```
#include <iostream>
#include <string>
#include <vector>
#include <sstream>

// To preserve key insertion order in a JSON object, we use a vector of pairs.
struct JsonValue {
    enum Type { Null, Boolean, Number, String, Array, Object } type;
    bool boolVal;
    double numVal;
    std::string strVal;
    std::vector<JsonValue> arrVal;
    std::vector<std::pair<std::string, JsonValue>> objVal;

    // Constructors for various types
    JsonValue() : type(Null) {}
    JsonValue(std::nullptr_t) : type(Null) {}
    JsonValue(bool b) : type(Boolean), boolVal(b) {}
    JsonValue(double d) : type(Number), numVal(d) {}
    JsonValue(const std::string &s) : type(String), strVal(s) {}
    JsonValue(const char* s) : type(String), strVal(s) {}
    JsonValue(const std::vector<JsonValue>& arr) : type(Array), arrVal(arr) {}
    JsonValue(const std::vector<std::pair<std::string, JsonValue>>& obj) : type(Object), objVal(obj) {}
};
```

```

std::string myStringify(const JsonValue &value) {
    std::ostringstream oss;
    switch(value.type) {
        case JsonValue::Null:
            return "null";
        case JsonValue::Boolean:
            return value.boolVal ? "true" : "false";
        case JsonValue::Number:
            oss << value.numVal;
            return oss.str();
        case JsonValue::String:
            return "\"" + value.strVal + "\"";
        case JsonValue::Array: {
            std::string res = "[";
            for (size_t i = 0; i < value.arrVal.size(); i++) {
                res += myStringify(value.arrVal[i]);
                if(i < value.arrVal.size() - 1)
                    res += ",";
            }
            res += "]";
            return res;
        }
        case JsonValue::Object: {
            std::string res = "{";
            for (size_t i = 0; i < value.objVal.size(); i++) {
                res += "\"" + value.objVal[i].first + "\": " + myStringify(value.objVal[i].second);
                if(i < value.objVal.size() - 1)
                    res += ",";
            }
            res += "}";
            return res;
        }
    }
    return "";
}

int main(){
    // Example: {"y":1,"x":2}
    JsonValue jsonObj({
        {"y", JsonValue(1)},
        {"x", JsonValue(2)}
    });
    std::cout << myStringify(jsonObj) << std::endl;
    return 0;
}

```

Promise Pool

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[JavaScript](#) · [Concurrency](#)

Lists: Premium 98

Problem:

Given an array of asynchronous functions and a pool limit n , return an asynchronous function `promisePool`. It should return a promise that resolves when all the input functions resolve.

Pool limit is defined as the maximum number promises that can be pending at once. `promisePool` should begin execution of as many functions as possible and continue executing new functions when old promises resolve. `promisePool` should execute `functions[i]` then `functions[i + 1]` then `functions[i + 2]`, etc. When the last promise resolves, `promisePool` should also resolve.

For example, if $n = 1$, `promisePool` will execute one function at a time in series. However, if $n = 2$, it first executes two functions. When either of the two functions resolve, a 3rd function should be executed (if available), and so on until there are no functions left to execute.

You can assume all functions never reject. It is acceptable for `promisePool` to return a promise that resolves any value.

Example 1:

```
Input:
functions = [
  () => new Promise(res => setTimeout(res, 300)),
  () => new Promise(res => setTimeout(res, 400)),
  () => new Promise(res => setTimeout(res, 200))
]
n = 2
```

Output: `[[300,400,500],500]`

Explanation:

Three functions are passed in. They sleep for 300ms, 400ms, and 200ms respectively.

They resolve at 300ms, 400ms, and 500ms respectively. The returned promise resolves at 500ms.

At $t=0$, the first 2 functions are executed. The pool size limit of 2 is reached.

At $t=300$, the 1st function resolves, and the 3rd function is executed. Pool size is 2.

At $t=400$, the 2nd function resolves. There is nothing left to execute. Pool size is 1.

At $t=500$, the 3rd function resolves. Pool size is zero so the returned promise also resolves.

Example 2:

```
Input:
functions = [
  () => new Promise(res => setTimeout(res, 300)),
  () => new Promise(res => setTimeout(res, 400)),
  () => new Promise(res => setTimeout(res, 200))
]
n = 5
```

Output: `[[300,400,200],400]`

Explanation:

The three input promises resolve at 300ms, 400ms, and 200ms respectively.

The returned promise resolves at 400ms.

At $t=0$, all 3 functions are executed. The pool limit of 5 is never met.

At $t=200$, the 3rd function resolves. Pool size is 2.

At $t=300$, the 1st function resolved. Pool size is 1.

At $t=400$, the 2nd function resolves. Pool size is 0, so the returned promise also resolves.

Example 3:

```
Input:
functions = [
```

```

    () => new Promise(res => setTimeout(res, 300)),
    () => new Promise(res => setTimeout(res, 400)),
    () => new Promise(res => setTimeout(res, 200))
  ]
  n = 1

```

Output: `[[300,700,900],900]`

Explanation:

The three input promises resolve at 300ms, 700ms, and 900ms respectively.

The returned promise resolves at 900ms.

At t=0, the 1st function is executed. Pool size is 1.

At t=300, the 1st function resolves and the 2nd function is executed. Pool size is 1.

At t=700, the 2nd function resolves and the 3rd function is executed. Pool size is 1.

At t=900, the 3rd function resolves. Pool size is 0 so the returned promise resolves.

Constraints:

- `0 <= functions.length <= 10`
- `1 <= n <= 10`

TypeScript

TypeScript

```

type F = () => Promise<any>;

function promisePool(functions: F[], n: number): Promise<any> {
  const next = () => functions[n++]?.().then(next);
  return Promise.all(functions.slice(0, n).map((f) => f().then(next)));
}

```

TypeScript

```

type F = () => Promise<any>;

function promisePool(functions: F[], n: number): Promise<any> {
  const wrappers = functions.map(fn => async () => {
    await fn();
    const nxt = waiting.shift();
    nxt && (await nxt());
  });

  const running = wrappers.slice(0, n);
  const waiting = wrappers.slice(n);
  return Promise.all(running.map(fn => fn()));
}

```

TypeScript

```

type F = () => Promise<any>;

function promisePool(functions: F[], n: number): Promise<any> {
  const wrappers = functions.map(fn => async () => {
    await fn();
    const nxt = waiting.shift();
    nxt && (await nxt());
  });

  const running = wrappers.slice(0, n);
  const waiting = wrappers.slice(n);
  return Promise.all(running.map(fn => fn()));
}

```

Python

Python

```

import asyncio

async def promise_pool(functions, n):
    # Shared index among all tasks.
    i = 0

    async def worker():
        nonlocal i
        while i < len(functions):
            # Fetch the current function and increment the index for next worker.
            fn = functions[i]
            i += 1
            # Await the async function.
            await fn()

    # Create n worker tasks.
    tasks = [asyncio.create_task(worker()) for _ in range(n)]
    # Wait until all worker tasks finish.
    await asyncio.gather(*tasks)

# Example usage:
if __name__ == "__main__":
    async def async_task(delay):
        await asyncio.sleep(delay)

    functions = [
        lambda: async_task(0.3),
        lambda: async_task(0.4),
        lambda: async_task(0.2)
    ]
    asyncio.run(promise_pool(functions, 2))

```

[*] JavaScript — Pattern Solution (matched from community answers)

Python

```
import asyncio

async def promise_pool(functions, n):
    # Shared index among all tasks.
    i = 0

    async def worker():

Array of Objects to Matrix

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[JavaScript](#) · [Array](#)

Lists: Premium 98

Problem:

Write a function that converts an array of objects `arr` into a matrix `m`.

`arr` is an array of objects or arrays. Each item in the array can be deeply nested with child arrays and child objects. It can also contain numbers, strings, booleans, and null values.

The first row `m` should be the column names. If there is no nesting, the column names are the unique keys within the objects. If there is nesting, the column names are the respective paths in the object separated by ".".

Each of the remaining rows corresponds to an object in `arr`. Each value in the matrix corresponds to a value in an object. If a given object doesn't contain a value for a given column, the cell should contain an empty string "".

The columns in the matrix should be in lexicographically ascending order.

Example 1:

Input:

```
arr = [
  {"b": 1, "a": 2},
  {"b": 3, "a": 4}
]
```

Output:

```
[
  ["a", "b"],
  [2, 1],
  [4, 3]
]
```

Explanation:

There are two unique column names in the two objects: "a" and "b".

"a" corresponds with [2, 4].

"b" corresponds with [1, 3].

Example 2:

Input:

```
arr = [
  {"a": 1, "b": 2},
  {"c": 3, "d": 4},
  {}
]
```

Output:

```
[
  ["a", "b", "c", "d"],
  [1, 2, "", ""],
  [ "", "", 3, 4],
  [ "", "", "", "" ]
]
```

Explanation:

There are 4 unique column names: "a", "b", "c", "d".

The first object has values associated with "a" and "b".

The second object has values associated with "c" and "d".

The third object has no keys, so it is just a row of empty strings.

Example 3:

Input:

```
arr = [
  {"a": {"b": 1, "c": 2}},
  {"a": {"b": 3, "d": 4}}
]
```

Output:

```
[
  ["a.b", "a.c", "a.d"],
  [1, 2, ""],
  [3, "", 4]
]
```

Explanation:

In this example, the objects are nested. The keys represent the full path to each value separated by periods.

There are three paths: "a.b", "a.c", "a.d".

Example 4:

Input:

```
arr = [
  [{"a": null}],
  [{"b": true}],
  [{"c": "x"}]
]
```

Output:

```
[
  ["0.a", "0.b", "0.c"],
  [null, "", ""],
  ["", true, ""],
  ["", "", "x"]
]
```

Explanation:

Arrays are also considered objects with their keys being their indices.

Each array has one element so the keys are "0.a", "0.b", and "0.c".

Example 5:

Input:

```
arr = [
  {},
  {},
  {}
]
```

Output:

```
[
  [],
  [],
  [],
  []
]
```

Explanation:

There are no keys so every row is an empty array.

Constraints:

- arr is a valid JSON array
- $1 \leq \text{arr.length} \leq 1000$
- unique keys ≤ 1000

TypeScript

TypeScript

```

function jsonToMatrix(arr: any[]): (string | number | boolean | null)[][] {
  const isObject = (o: any) => o !== null && typeof o === 'object';

  // Returns the keys of a JSON-like object by recursively unwrapping the nests.
  const getKeys = (json: any): string[] => {
    if (!isObject(json)) {
      return [''];
    }
    return Object.keys(json).reduce((acc: string[], currKey: string) => {
      return (
        acc.push(
          ...getKeys(json[currKey]).map((nextKey: string) =>
            nextKey === '' ? currKey : `${currKey}.${nextKey}`
          )
        ),
        acc
      );
    }, []);
  };

  const sortedKeys: string[] = [
    ...arr.reduce((acc: Set<string>, curr: any) => {
      getKeys(curr).forEach((key: string) => acc.add(key));
      return acc;
    }, new Set<string>()),
  ].sort();

  // Returns the value of `obj` keyed by `nestedKey`.
  const getValue = (
    obj: any,
    nestedKey: string
  ): string | number | boolean | null => {
    let value: any = obj;
    for (const key of nestedKey.split('.')) {
      if (!isObject(value) || !(key in value)) {
        return '';
      }
      value = value[key];
    }
    return isObject(value) ? '' : value;
  };

  const matrix: (string | number | boolean | null)[][] = [sortedKeys];
  arr.forEach((obj: any) => {
    matrix.push(
      sortedKeys.map((nestedKey: string) => getValue(obj, nestedKey))
    );
  });

  return matrix;
}

```

TypeScript

```

function jsonToMatrix(arr: any[]): (string | number | boolean | null)[] {
  const dfs = (key: string, obj: any) => {
    if (
      typeof obj === 'number' ||
      typeof obj === 'string' ||
      typeof obj === 'boolean' ||
      obj === null

MEDIUM

Differences Between Two Objects

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

JavaScript

Lists: Premium 98

Problem:

Write a function that accepts two deeply nested objects or arrays `obj1` and `obj2` and returns a new object representing their differences.

The function should compare the properties of the two objects and identify any changes. The returned object should only contains keys where the value is different from `obj1` to `obj2`.

For each changed key, the value should be represented as an array [`obj1` value, `obj2` value]. Keys that exist in one object but not in the other should not be included in the returned object. The end result should be a deeply nested object where each leaf value is a difference array.

When comparing two arrays, the indices of the arrays are considered to be their keys.

You may assume that both objects are the output of `JSON.parse`.

Example 1:

Input:

```
obj1 = {}
```

```
obj2 = {
```

```
  "a": 1,
```

```
  "b": 2
```

```
}
```

Output: {}

Explanation: There were no modifications made to `obj1`. New keys "a" and "b" appear in `obj2`, but keys that are added or removed should be ignored.

Example 2:

Input:

```
obj1 = {
```

```
  "a": 1,
```

```
  "v": 3,
```

```
  "x": [],
```

```
  "z": {
```

```
    "a": null
```

```
  }
```

```
}
```

```
obj2 = {
```

```
  "a": 2,
```

```
  "v": 4,
```

```
  "x": [],
```

```
  "z": {
```

```
    "a": 2
```

```
  }
```

```
}
```

Output:

```
{
```

```
    "a": [1, 2],
  "v": [3, 4],
  "z": {
    "a": [null, 2]
  }
}
```

Explanation: The keys "a", "v", and "z" all had changes applied. "a" was changed from 1 to 2. "v" was changed from 3 to 4. "z" had a change applied to a child object. "z.a" was changed from null to 2.

Example 3:

Input:

```
obj1 = {
  "a": 5,
  "v": 6,
  "z": [1, 2, 4, [2, 5, 7]]
}
obj2 = {
  "a": 5,
  "v": 7,
  "z": [1, 2, 3, [1]]
}
```

Output:

```
{
  "v": [6, 7],
  "z": {
    "2": [4, 3],
    "3": {
      "0": [2, 1]
    }
  }
}
```

Explanation: In obj1 and obj2, the keys "v" and "z" have different assigned values. "a" is ignored because the value is unchanged. In the key "z", there is a nested array. Arrays are treated like objects where the indices are keys. There were two alterations to the the array: z[2] and z[3][0]. z[0] and z[1] were unchanged and thus not included. z[3][1] and z[3][2] were removed and thus not included.

Example 4:

Input:

```
obj1 = {
  "a": {"b": 1},
}
obj2 = {
  "a": [5],
}
```

Output:

```
{
  "a": [{"b": 1}, [5]]
}
```

Explanation: The key "a" exists in both objects. Since the two associated values have

different types, they are placed in the difference array.

Example 5:

Input:

```
obj1 = {
  "a": [1, 2, {}],
  "b": false
}
obj2 = {
  "b": false,
  "a": [1, 2, {}]
}
```

Output:

```
{}
```

Explanation: Apart from a different ordering of keys, the two objects are identical so an empty object is returned.

Constraints:

- obj1 and obj2 are valid JSON objects or arrays
- $2 \leq \text{JSON.stringify(obj1).length} \leq 104$
- $2 \leq \text{JSON.stringify(obj2).length} \leq 104$

Quick Review — JavaScript 7 questions · insights · complexity · solution

#2627 Debounce [Medium]

Key Insights

- Each call to the debounced function resets the timer.
- Only the most recent function call (that isn't subsequently cancelled) will eventually execute.
- Passing of parameters is handled by storing the arguments of the latest call.
- The solution leverages timers (or equivalent scheduling mechanisms) and cancellation techniques.

Space & Time

Time Complexity: $O(1)$ per call, as each invocation only clears and sets a timer.

Space Complexity: $O(1)$, since only a single timer reference is maintained.

Solution

The solution creates a wrapper function that maintains an internal timer reference. On each call to the debounced function, if a timer exists, it is cancelled. A new timer is then set to execute the original function after t milliseconds with the provided arguments. This ensures that only the last invocation runs if multiple calls occur within the delay period.

#2628 JSON Deep Equal [Medium]

Key Insights

- Use recursion to compare nested structures.
- For primitive types, a simple equality check (`===` in JavaScript, `==` in Python, etc.) suffices.
- For arrays, verify both have the same length and compare each element recursively.
- For objects, ensure both have the same keys (order does not matter) then recursively compare the corresponding values.
- Handle cases where one operand is null or differs by type early to avoid unnecessary recursion.

Space & Time

Time Complexity: $O(N)$ in the worst-case, where N is the total number of elements/values in the JSON structure.

Space Complexity: $O(N)$ due to the recursion call stack in the worst-case scenario of deeply nested objects or arrays.

Solution

We solve this problem using a recursive approach. The algorithm first checks if both values are strictly equal, which handles primitives immediately. For arrays and objects, it verifies that the sizes (length for arrays and number of keys for objects) match. Then it recurses into each element (for arrays) or checks each key-value pair (for objects) to ensure that they are also deeply equal. For objects, the order of keys is irrelevant, so we compare key sets. This method naturally handles nested structures by delegating equality checks to the same function.

#2630 Memoize [Medium]

Key Insights

- Cache previously computed results using a data structure keyed by the function arguments.
- Ensure the key uniquely represents the argument order; simple tuple (or equivalent) suffices.
- Use closures (or object state) to maintain both the cache and a call count tracking actual function invocations.
- Expose a method (`getCallCount`) on the memoized function to report the number of times the original function was actually called.
- The memoized version works for functions that might take one or more parameters.

Space & Time

Time Complexity: $O(1)$ average for each call assuming efficient hashing of arguments.

Space Complexity: $O(n)$ for caching n distinct input combinations.

Solution

We use a hash-based cache (a dictionary or map) to store results for every unique set of arguments. Upon each call, we check if the key (constructed from the input arguments) exists in the cache. If not, we increment a counter, call the original function, store the result in the cache, and return it. Otherwise, we return the cached result. The memoized function is augmented with a `getCallCount` method to report the number of actual calls made to the original function.

#2633 Convert Object to JSON String [Medium]

Key Insights

- The solution must support all JSON primitives: strings, numbers, booleans, and null.
- Composite types such as arrays and objects require recursive traversal for proper serializing.
- For strings, wrap them in double quotes.
- For arrays, recursively process every element and join them with commas between square brackets.
- For objects, iterate keys in insertion order and combine key-value pairs (key must be a string in double quotes) with commas between curly braces.
- Use recursion carefully to handle nested structures without adding unnecessary spaces.

Space & Time

Time Complexity: $O(n)$, where n is the total number of elements/characters in the JSON structure.

Space Complexity: $O(n)$ due to the recursion stack and the constructed output string.

Solution

We use a recursive approach that inspects the type of the value and processes it accordingly:

– If the value is null, output "null". – If the value is a boolean or number, convert it directly to its string representation. – For a string, ensure it is enclosed in double quotes. – For an array, iterate over each element, serialize each recursively, join them with commas, and enclose in square brackets. – For an object, iterate over its keys in insertion order (or using `Object.keys` in JS / `LinkedHashMap` in Java), serialize both key (wrapped in double quotes) and its corresponding value, join with commas, and enclose in curly braces. This approach leverages recursion to handle arbitrarily nested objects and arrays while ensuring there are no extra spaces in the final string.

#2636 Promise Pool [Medium]

Key Insights

- Use a concurrency control mechanism to limit the number of actively running promises.
- Maintain an index or pointer to track which function from the input array should be executed next.
- Upon the resolution of any promise, start a new one if available until all functions have been processed.
- The overall task is complete when there are no functions left and all running promises have resolved.

Space & Time

Time Complexity: $O(m)$, where m is the number of functions to execute.

Space Complexity: $O(n)$ for the active pool of concurrent promises.

Solution

We can solve the problem by maintaining an index that tracks which asynchronous function to execute next. We define a helper routine (or executor) that:

– Checks if there is a function left to run. – If yes, increments the index and awaits the result of running that function. – Once the function completes, the routine recursively calls itself to pick up the next function. We start n such routines (to respect the pool limit) and use `Promise.all` (or the equivalent in other languages) to wait until all concurrent routines have finished executing. This structure ensures that we never run more than n promises concurrently and that a new promise starts as soon as one finishes.

#2675 Array of Objects to Matrix [Medium]

Key Insights

- Flatten each object or array into dot-separated paths such as ``a.b`` or ``a.0.c``.
- Use DFS so nested objects and nested arrays are handled uniformly.
- For each row, store a map from flattened path to value.
- Collect every path seen across all rows into a set of column names.
- Sort the column names lexicographically to build the header row.
- For each flattened row map, output values in header order and use an empty string when a column is missing.

Space & Time

Time Complexity: $O(T + R * C \log C)$, where T is the total number of nested nodes visited, R is the number of rows, and C is the number of unique flattened columns.

Space Complexity: $O(R * C + C)$ in the worst case for the flattened row maps and the set of all column names.

Solution

We solve the problem by flattening every input row first. A DFS walks through objects and arrays, extending the current path with either the property name or the array index. When the DFS reaches a primitive value or ``null``, it stores that value under the built path. While flattening each row, we also collect every path into a global set of column names. After all rows are processed, we sort the columns lexicographically, place them in the first row of the matrix, and then build each remaining row by reading values from that row's flattened map, using ```` for missing paths.

#2700 Differences Between Two Objects [Medium]

Key Insights

- Use recursion to traverse nested objects and arrays.
- Compare only keys that exist in both objects.
- When encountering two values of different types or unequal primitives, record the difference as `[value from obj1, value from obj2]`.
- When both values are objects or arrays, recursively compute their differences and include them only if the resulting nested diff is non-empty.
- Arrays are treated like objects with indices as keys.
- The solution requires careful type checking and handling of recursive structures.

Space & Time

Time Complexity: $O(n)$ in average, where n is the number of keys/elements in the common parts of the structures.

Space Complexity: $O(n)$ due to recursion and storage needed for the output differences.

Solution

We solve the problem using a recursive function that compares keys present in both input objects. For each common key:

– If both values are objects (or both are arrays), recursively compute their differences. – If the recursive call returns a non-empty object, include that key in the result. – If the two values are of different types or are primitives that differ, add the key with a difference array `[value from obj1, value from obj2]`. – Ignore keys that exist only in one object. This recursive approach naturally handles the deeply nested structure while ensuring only common keys with different values are captured.

EASY

Ransom Note

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Counting](#)

Lists: Grind 169

Problem:

Given two strings ransomNote and magazine, return true if ransomNote can be constructed by using the letters from magazine and false otherwise.

Each letter in magazine can only be used once in ransomNote.

Example 1:

Input: ransomNote = "a", magazine = "b"

Output: false

Example 2:

Input: ransomNote = "aa", magazine = "ab"

Output: false

Example 3:

Input: ransomNote = "aa", magazine = "aab"

Output: true

Constraints:

- $1 \leq \text{ransomNote.length}, \text{magazine.length} \leq 105$
- ransomNote and magazine consist of lowercase English letters.

Python

Python

```
# Function to check if ransom note can be constructed from magazine
def canConstruct(ransomNote: str, magazine: str) -> bool:
    # Create a dictionary to hold the frequency of each character in magazine
    char_frequency = {}
    for char in magazine:
        char_frequency[char] = char_frequency.get(char, 0) + 1

    # Check each character in ransomNote against the frequency map
    for char in ransomNote:
        if char_frequency.get(char, 0) == 0:
            return False # Character not available or used up
        char_frequency[char] -= 1 # Use the character

    return True

# Example usage:
if __name__ == "__main__":
    print(canConstruct("aa", "aab")) # Expected output: True
```

Python

```
class Solution:

[*] String — Pattern Solution (stored optimal)

Python

```
# Function to check if ransom note can be constructed from magazine
def canConstruct(ransomNote: str, magazine: str) -> bool:
    # Create a dictionary to hold the frequency of each character in magazine
    char_frequency = {}
    for char in magazine:
        char_frequency[char] = char_frequency.get(char, 0) + 1

    # Check each character in ransomNote against the frequency map
    for char in ransomNote:
        if char_frequency.get(char, 0) == 0:
            return False # Character not available or used up
        char_frequency[char] -= 1 # Use the character

    return True

# Example usage:
if __name__ == "__main__":
    print(canConstruct("aa", "aab")) # Expected output: True
```

C++

```

// Function to check if ransom note can be constructed from magazine
#include <iostream>
#include <string>
#include <unordered_map>
using namespace std;

bool canConstruct(string ransomNote, string magazine) {
    // Use an unordered_map to hold frequency counts of each character in magazine
    unordered_map<char, int> frequency;
    for (char ch : magazine) {
        frequency[ch]++;
    }

    // Iterate through each character in ransom note and decrease its count
    for (char ch : ransomNote) {
        if (frequency[ch] == 0) {
            return false; // Character not available or already fully used
        }
        frequency[ch]--;
    }

    return true;
}

// Example usage:

int main() {
    cout << boolalpha << canConstruct("aa", "aab") << endl; // Expected output: true
    return 0;
}

EASY

Sentence Similarity

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [String](#)

Lists: Premium 98

Problem:

We can represent a sentence as an array of words, for example, the sentence "I am happy with leetcode" can be represented as `arr = ["I", "am", "happy", "with", "leetcode"]`.

Given two sentences `sentence1` and `sentence2` each represented as a string array and given an array of string pairs `similarPairs` where `similarPairs[i] = [xi, yi]` indicates that the two words `xi` and `yi` are similar.

Return true if `sentence1` and `sentence2` are similar, or false if they are not similar.

Two sentences are similar if:

- They have the same length (i.e., the same number of words)
- `sentence1[i]` and `sentence2[i]` are similar.

Notice that a word is always similar to itself, also notice that the similarity relation is not transitive. For example, if the words `a` and `b` are similar, and the words `b` and `c` are similar, `a` and `c` are not necessarily similar.

Example 1:

Input: sentence1 = ["great","acting","skills"], sentence2 = ["fine","drama","talent"], similarPairs = [["great","fine"],["drama","acting"],["skills","talent"]]

Output: true

Explanation: The two sentences have the same length and each word i of sentence1 is also similar to the corresponding word in sentence2.

Example 2:

Input: sentence1 = ["great"], sentence2 = ["great"], similarPairs = []

Output: true

Explanation: A word is similar to itself.

Example 3:

Input: sentence1 = ["great"], sentence2 = ["doubleplus","good"], similarPairs = [["great","doubleplus"]]

Output: false

Explanation: As they don't have the same length, we return false.

Constraints:

- $1 \leq \text{sentence1.length}, \text{sentence2.length} \leq 1000$
- $1 \leq \text{sentence1}[i].\text{length}, \text{sentence2}[i].\text{length} \leq 20$
- $\text{sentence1}[i]$ and $\text{sentence2}[i]$ consist of English letters.
- $0 \leq \text{similarPairs.length} \leq 1000$
- $\text{similarPairs}[i].\text{length} == 2$
- $1 \leq \text{xi.length}, \text{yi.length} \leq 20$
- xi and yi consist of lower-case and upper-case English letters.
- All the pairs (xi, yi) are distinct.

Single Row Keyboard

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#)

Lists: Premium 98

Problem:

There is a special keyboard with all keys in a single row.

Given a string keyboard of length 26 indicating the layout of the keyboard (indexed from 0 to 25). Initially, your finger is at index 0. To type a character, you have to move your finger to the index of the desired character. The time taken to move your finger from index i to index j is $|i - j|$.

You want to type a string word. Write a function to calculate how much time it takes to type it with one finger.

Example 1:

Input: keyboard = "abcdefghijklmnopqrstuvwxyz", word = "cba"

Output: 4

Explanation: The index moves from 0 to 2 to write 'c' then to 1 to write 'b' then to 0 again to write 'a'.

Total time = 2 + 1 + 1 = 4.

Example 2:

Input: keyboard = "pqrstuvwxyzabcdefghijklmnopqrstuvwxyz", word = "leetcode"

Output: 73

Constraints:

- keyboard.length == 26
- keyboard contains each English lowercase letter exactly once in some order.
- 1 <= word.length <= 104
- word[i] is an English lowercase letter.

Python

Python

```
# Build a dictionary to map each character to its index in the keyboard string.
def calculateTime(keyboard: str, word: str) -> int:
    # Create a mapping for character to index
    char_index = {char: idx for idx, char in enumerate(keyboard)}

    # Initialize the total time and starting position
    total_time = 0
    current_position = 0

    # Iterate over each character in the word
    for char in word:
        # Find the target index for the character
        target_position = char_index[char]
        # Calculate the time to move to the target position
        total_time += abs(target_position - current_position)
        # Update current position to the target position
        current_position = target_position

    return total_time

# Example usage:
# print(calculateTime("abcdefghijklmnopqrstuvwxyz", "cba"))
```

Python

```

class Solution:
    def calculateTime(self, keyboard: str, word: str) -> int:
        letterToIndex = {c: i for i, c in enumerate(keyboard)}
        return (letterToIndex[word[0]] +
                sum(abs(letterToIndex[a] - letterToIndex[b])
                    for a, b in itertools.pairwise(word)))

```

Python

```

String to Integer (atoi)

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[String](#)

Lists: Grind 169

Problem:

Implement the `myAtoi(string s)` function, which converts a string to a 32-bit signed integer.

The algorithm for `myAtoi(string s)` is as follows:

1. **Whitespace:** Ignore any leading whitespace (" ").
2. **Signedness:** Determine the sign by checking if the next character is '-' or '+', assuming positivity if neither present.
3. **Conversion:** Read the integer by skipping leading zeros until a non-digit character is encountered or the end of the string is reached. If no digits were read, then the result is 0.

4. Rounding: If the integer is out of the 32-bit signed integer range $[-2^{31}, 2^{31} - 1]$, then round the integer to remain in the range. Specifically, integers less than -2^{31} should be rounded to -2^{31} , and integers greater than $2^{31} - 1$ should be rounded to $2^{31} - 1$.

Return the integer as the final result.

Example 1:

Input: `s = "42"`

Output: 42

Explanation:

The underlined characters are what is read in and the caret is the current reader position.

Step 1: `"42"` (no characters read because there is no leading whitespace)

^

Step 2: `"42"` (no characters read because there is neither a '-' nor '+')

^

Step 3: `"42"` ("`42`" is read in)

^

Example 2:

Input: `s = "-042"`

Output: -42

Explanation:

Step 1: `"-042"` (leading whitespace is read and ignored)

^

Step 2: `"-042"` ('-' is read, so the result should be negative)

^

Step 3: `"-042"` ("`042`" is read in, leading zeros ignored in the result)

^

Example 3:

Input: `s = "1337c0d3"`

Output: 1337

Explanation:

Step 1: `"1337c0d3"` (no characters read because there is no leading whitespace)

^

Step 2: `"1337c0d3"` (no characters read because there is neither a '-' nor '+')

^

Step 3: `"1337c0d3"` ("`1337`" is read in; reading stops because the next character is a non-digit)

^

Example 4:

Input: `s = "0-1"`

Output: 0

Explanation:

Step 1: `"0-1"` (no characters read because there is no leading whitespace)

^

Step 2: "0-1" (no characters read because there is neither a '-' nor '+')

^

Step 3: "0-1" ("0" is read in; reading stops because the next character is a non-digit)

^

Example 5:

Input: s = "words and 987"

Output: 0

Explanation:

Reading stops at the first non-digit character 'w'.

Constraints:

- $0 \leq s.length \leq 200$
- s consists of English letters (lower-case and upper-case), digits (0-9), ' ', '+', '-', and '.'.

Python

Python

```
# Python solution for the myAtoi problem.
def myAtoi(s: str) -> int:
    INT_MAX = 2**31 - 1
    INT_MIN = -2**31

    i, n = 0, len(s)
    # Skip leading whitespace.
    while i < n and s[i] == ' ':
        i += 1

    # Handle sign.
    sign = 1
    if i < n and (s[i] == '+' or s[i] == '-'):
        if s[i] == '-':
            sign = -1
        i += 1

    result = 0
    # Convert digits and build the integer.
    while i < n and s[i].isdigit():
        digit = int(s[i])
        # Check for overflow or underflow.
        if result > (INT_MAX - digit) // 10:
            return INT_MAX if sign == 1 else INT_MIN
        result = result * 10 + digit

        i += 1

    return sign * result

# Example usage:
print(myAtoi("42"))
print(myAtoi(" -042"))
print(myAtoi("1337c0d3"))
print(myAtoi("0-1"))
print(myAtoi("words and 987"))
```

Python

```
class Solution:
    def myAtoi(self, s: str) -> int:
        s = s.strip()
        if not s:
            return 0

        sign = -1 if s[0] == '-' else 1
        if s[0] in {'-', '+'}:
            s = s[1:]

        num = 0

        for c in s:
            if not c.isdigit():
                break
            num = num * 10 + int(c)
            if sign * num <= -2**31:

Group Shifted Strings

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [String](#)

Lists: Premium 98

Problem:

Perform the following shift operations on a string:

- Right shift: Replace every letter with the successive letter of the English alphabet, where 'z' is replaced by 'a'. For example, "abc" can be right-shifted to "bcd" or "xyz" can be right-shifted to "yza".
- Left shift: Replace every letter with the preceding letter of the English alphabet, where 'a' is replaced by 'z'. For example, "bcd" can be left-shifted to "abc" or "yza" can be left-shifted to "xyz".

We can keep shifting the string in both directions to form an endless shifting sequence.

- For example, shift "abc" to form the sequence: ... <-> "abc" <-> "bcd" <-> ... <-> "xyz" <-> "yza" <-> ... <-> "zab" <-> "abc" <-> ...

You are given an array of strings `strings`, group together all `strings[i]` that belong to the same shifting sequence. You may return the answer in any order.

Example 1:

Input: `strings = ["abc","bcd","acef","xyz","az","ba","a","z"]`

Output: `[["acef"],["a","z"],["abc","bcd","xyz"],["az","ba"]]`

Example 2:

Input: `strings = ["a"]`

Output: `[["a"]]`

Constraints:

- `1 <= strings.length <= 200`
- `1 <= strings[i].length <= 50`
- `strings[i]` consists of lowercase English letters.

Encode and Decode Strings

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [String](#) · [Design](#)

Lists: Grind 169 | Premium 98

Problem:

Design an algorithm to encode a list of strings to a string. The encoded string is then sent over the network and is decoded back to the original list of strings.

Machine 1 (sender) has the function:

```
string encode(vector<string> strs) {
    // ... your code
    return encoded_string;
}
```

Machine 2 (receiver) has the function:

```
vector<string> decode(string s) {
    //... your code
    return strs;
}
```

```
}
```

So Machine 1 does:

```
string encoded_string = encode(strs);
```

and Machine 2 does:

```
vector<string> str2 = decode(encoded_string);
```

strs2 in Machine 2 should be the same as strs in Machine 1.

Implement the encode and decode methods.

You are not allowed to solve the problem using any serialize methods (such as eval).

Example 1:

```
Input: dummy_input = ["Hello","World"]
```

```
Output: ["Hello","World"]
```

Explanation:

Machine 1:

```
Codec encoder = new Codec();
```

```
String msg = encoder.encode(strs);
```

Machine 1 ---msg---> Machine 2

Machine 2:

```
Codec decoder = new Codec();
```

```
String[] str2 = decoder.decode(msg);
```

Example 2:

```
Input: dummy_input = [""]
```

```
Output: [""]
```

Constraints:

- $1 \leq \text{strs.length} \leq 200$
- $0 \leq \text{strs}[i].\text{length} \leq 200$
- `strs[i]` contains any possible characters out of 256 valid ASCII characters.

Follow up: Could you write a generalized algorithm to work on any possible set of characters?

Python

Python

```

class Codec:
    # Encodes a list of strings to a single string.
    def encode(self, strs):
        encoded = []
        # Iterate through each string in the list.
        for s in strs:
            # Append the length of the string, a '#' as delimiter, and the string.
            encoded.append(str(len(s)) + '#' + s)
        # Join all parts into one encoded string.
        return ''.join(encoded)

    # Decodes a single string back to a list of strings.
    def decode(self, s):
        decoded = []

Design Log Storage System

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Problem:

You are given several logs, where each log contains a unique ID and timestamp. Timestamp is a string that has the following format: Year:Month:Day:Hour:Minute:Second, for example, 2017:01:01:23:59:59. All domains are zero-padded decimal numbers.

Implement the LogSystem class:

- `LogSystem()` Initializes the LogSystem object.
- `void put(int id, string timestamp)` Stores the given log (id, timestamp) in your storage system.
- `int[] retrieve(string start, string end, string granularity)` Returns the IDs of the logs whose timestamps are within the range from start to end inclusive. start and end all have the same format as timestamp, and granularity means how precise the range should be (i.e. to the exact Day, Minute, etc.). For example, start = "2017:01:01:23:59:59", end = "2017:01:02:23:59:59", and granularity = "Day" means that we need to find the logs within the inclusive range from Jan. 1st 2017 to Jan. 2nd 2017, and the Hour, Minute, and Second for each log entry can be ignored.

Example 1:

Input

```
["LogSystem", "put", "put", "put", "retrieve", "retrieve"]
[[], [1, "2017:01:01:23:59:59"], [2, "2017:01:01:22:59:59"], [3, "2016:01:01:00:00:00"],
["2016:01:01:01:01:01", "2017:01:01:23:00:00", "Year"], ["2016:01:01:01:01:01",
"2017:01:01:23:00:00", "Hour"]]
```

Output

```
[null, null, null, null, [3, 2, 1], [2, 1]]
```

Explanation

```
LogSystem logSystem = new LogSystem();
logSystem.put(1, "2017:01:01:23:59:59");
logSystem.put(2, "2017:01:01:22:59:59");
logSystem.put(3, "2016:01:01:00:00:00");
```

```
// return [3,2,1], because you need to return all logs between 2016 and 2017.
```

```
logSystem.retrieve("2016:01:01:01:01:01", "2017:01:01:23:00:00", "Year");
```

```
// return [2,1], because you need to return all logs between Jan. 1, 2016 01:XX:XX and Jan.
1, 2017 23:XX:XX.
```

```
// Log 3 is not returned because Jan. 1, 2016 00:00:00 comes before the start of the range.
logSystem.retrieve("2016:01:01:01:01:01", "2017:01:01:23:00:00", "Hour");
```

Constraints:

- $1 \leq id \leq 500$
- $2000 \leq Year \leq 2017$
- $1 \leq Month \leq 12$
- $1 \leq Day \leq 31$
- $0 \leq Hour \leq 23$
- $0 \leq Minute, Second \leq 59$
- granularity is one of the values ["Year", "Month", "Day", "Hour", "Minute", "Second"].

- At most 500 calls will be made to put and retrieve.

Python

Python

```
class LogSystem:
    def __init__(self):
        # List to store logs as (timestamp, id) tuples
        self.logs = []
        # Mapping granularity to index for the substring (fixed format: Year:Month:Day:Hour:Minute:Second)
        self.granularity_to_index = {
            "Year": 4,
            "Month": 7,
            "Day": 10,
            "Hour": 13,
            "Minute": 16,
            "Second": 19
        }

    def put(self, id, timestamp):
        # Append the log as a tuple
        self.logs.append((timestamp, id))

    def retrieve(self, start, end, granularity):
        # Determine the slicing index based on granularity
        idx = self.granularity_to_index[granularity]
        # Slice the given start and end timestamps
        start_slice = start[:idx]
        end_slice = end[:idx]
        result = []

        # Iterate over all logs and check if the timestamp slice is within the range
        for ts, log_id in self.logs:
            ts_slice = ts[:idx]
            if start_slice <= ts_slice <= end_slice:
                result.append(log_id)
        return result

# Example usage:
# logSystem = LogSystem()
# logSystem.put(1, "2017:01:01:23:59:59")
# logSystem.put(2, "2017:01:01:22:59:59")
# logSystem.put(3, "2016:01:01:00:00:00")
# print(logSystem.retrieve("2016:01:01:01:01:01", "2017:01:01:23:00:00", "Year")) # Output: [3, 2, 1]
# print(logSystem.retrieve("2016:01:01:01:01:01", "2017:01:01:23:00:00", "Hour")) # Output: [2, 1]
```

Python

```

Alphabet Board Path

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#)

Lists: Denny Zhang

Problem:

On an alphabet board, we start at position (0, 0), corresponding to character board[0][0].

Here, board = ["abcde", "fghij", "klmno", "pqrst", "uvwxy", "z"], as shown in the diagram below.

We may make the following moves:

- 'U' moves our position up one row, if the position exists on the board;
- 'D' moves our position down one row, if the position exists on the board;
- 'L' moves our position left one column, if the position exists on the board;
- 'R' moves our position right one column, if the position exists on the board;
- '!' adds the character `board[r][c]` at our current position (r, c) to the answer.

(Here, the only positions that exist on the board are positions with letters on them.)

Return a sequence of moves that makes our answer equal to target in the minimum number of moves. You may return any path that does so.

Example 1:

Input: `target = "leet"`

Output: `"DDR!UURRR!!DDD!"`

Example 2:

Input: `target = "code"`

Output: `"RR!DDRR!UUL!R!"`

Constraints:

- $1 \leq \text{target.length} \leq 100$
- target consists only of English lowercase letters.

Python

Python

```

# Python solution with clear variable names and inline comments.
class Solution:
    def alphabetBoardPath(self, target: str) -> str:

            result.append("!")
        return "".join(result)

```

Quick Review — String 8 questions · insights · complexity · solution

#383 Ransom Note [Easy]

Key Insights

- Use a hash table (or dictionary) to store the frequency of each character present in magazine.
- Iterate over every character in ransomNote and check if the corresponding count in the hash table is available and sufficient.
- Decrease the character count for every match; if any character count falls below zero, return false.
- If all characters in ransomNote can be accounted for, return true.

Space & Time

Time Complexity: $O(n + m)$, where n is the length of magazine and m is the length of ransomNote.

Space Complexity: $O(1)$, since the extra space required for the hash table is limited to at most 26 entries for lowercase English letters.

Solution

We construct a frequency map for the magazine string using a hash table. This frequency map records how many times each letter appears in magazine. Then we iterate through the ransomNote string, and for every letter, we check the corresponding frequency in the map. If a letter is not found or its frequency is zero, we immediately return false as it means the letter cannot be used to build the note. Otherwise, we decrement the frequency count by one. If we successfully process all characters in ransomNote, then it can be constructed from magazine, and we return true.

#734 Sentence Similarity [Easy]

Key Insights

- First, check if both sentences have the same length.
- A word is always similar to itself.
- Similarity is defined only by the given pairs; it is not transitive.
- Use a hash table (dictionary) to store bi-directional similar pairs for quick look-ups.

Space & Time

Time Complexity: $O(n + m)$, where n is the number of words in the sentences and m is the number of similar pairs.

Space Complexity: $O(m)$, for storing the similar pairs in a hash table.

Solution

– Check if the two sentences have the same length; if not, return false. – Build a hash table where each word maps to a set of words it is similar to. For each pair $[x, y]$ in similarPairs, add y to the set for x and x to the set for y . – Iterate over the words of both sentences simultaneously. For each corresponding pair, if the words are identical, continue; otherwise, check if one word appears in the similar set of the other. – If all pairs meet the similarity condition, return true; otherwise, return false.

#1165 Single Row Keyboard [Easy]

Key Insights

- Create a mapping (hash table/dictionary) from each character to its index on the keyboard for $O(1)$ lookups.
- The cost to type each character is the absolute difference between the current position and the target character's position on the keyboard.
- Start from index 0 and sum up the distances moved for each successive character in the word.

Space & Time

Time Complexity: $O(n)$, where n is the length of the word.

Space Complexity: $O(1)$ (constant space for a mapping of 26 characters).

Solution

We solve the problem by first building a dictionary that maps each character in the keyboard layout to its corresponding index. We then initialize a variable to track the current finger position (starting at 0). For each character in the word, we look up its index, calculate the absolute difference from the current position, add that distance to the total time, and update the current position. This approach uses a single pass over the word with constant time lookups, ensuring an efficient solution.

#8 String to Integer (atoi) [Medium]

Key Insights

- Skip leading spaces in the string.
- Detect and handle the optional sign indicator ('+' or '-').
- Read and convert digit characters until a non-digit is encountered.
- Handle cases with no digits or leading zeros.
- Clamp the result to fit within the 32-bit signed integer range.

Space & Time

Time Complexity: $O(n)$ where n is the length of the string.

Space Complexity: $O(1)$ as only a constant amount of extra space is used.

Solution

We iterate through the string to first eliminate any leading whitespace. Next, we check for a sign character to determine if the resulting integer should be negative. We then convert each consecutive digit into an integer, all the while updating the result and checking for potential overflow. If an overflow is detected, we immediately return the appropriate maximum or minimum 32-bit signed integer boundary value. This approach ensures that we strictly follow the conversion rules and efficiently handle edge cases.

#249 Group Shifted Strings [Medium]

Key Insights

- All strings in the same group have the same relative differences between adjacent characters.
- Normalize each string's pattern by converting it to a key representation based on the differences between consecutive letters.
- A single character string forms its own group as there are no differences to compute.

Space & Time

Time Complexity: $O(n * m)$ where n is the number of strings and m is the average length of the strings (to compute each string's key).

Space Complexity: $O(n * m)$ to store the keys and grouping in the hash table.

Solution

The solution involves iterating over each string and generating a unique key that represents the relative differences between adjacent characters. This key is calculated by computing the difference (mod 26) between every consecutive pair in the string. Strings that share the same key can be grouped together since they can be shifted into one another. A hash table (or dictionary) is used to store and group the strings by their computed key. This approach handles edge cases like single-character strings separately.

#271 Encode and Decode Strings [Medium]

Key Insights

- Use length-prefix encoding for each string to avoid ambiguity.
- Append a delimiter (e.g., "#") after the length to separate it from the string content.
- This method ensures that even if the original strings contain special characters, including the delimiter, the decoding remains unambiguous.
- The approach handles edge cases, such as empty strings.

Space & Time

Time Complexity: $O(n)$, where n is the total number of characters across all strings.

Space Complexity: $O(n)$, required for the encoded string and the resulting decoded list.

Solution

We encode by iterating over each string and building a new string that contains the length of the string, a delimiter (e.g., "#"), and then the string itself. This way, during decoding, we can safely determine how many characters to extract by first reading until the delimiter to get the length, and then reading that number of characters. This length-prefix approach avoids conflicts with potential characters in the strings.

#635 Design Log Storage System [Medium]

Key Insights

- Store logs in a simple data structure such as a list or array.
- Convert the timestamps into strings; due to fixed-length and zero padding, lexicographical string comparisons are valid.
- Use a mapping to determine the slice length for each granularity, e.g. "Year" corresponds to the first 4 characters, "Month" corresponds to the first 7 characters, etc.
- During retrieval, compare the relevant substring of each stored timestamp against the start and end query timestamp slices.
- The inclusive nature of the query simplifies checking conditions.

Space & Time

Time Complexity: $O(N)$ per retrieval query, where N is the number of logs stored (since each log is checked). In the worst case, all log entries are examined.

Space Complexity: $O(N)$ where N is the number of logs stored.

Solution

We implement a LogSystem class that supports putting log entries and retrieving them using a specified granularity.

- Data Structures: Use a list/array to store log entries as tuples (or objects) containing the timestamp and log ID. A dictionary/map is used to store the mapping from granularity string to the substring index (e.g., "Year" => 4, "Month" => 7, etc.).
- For the put() method, simply append the new log entry into the list.
- For the retrieve() method, compute the substring length based on the provided granularity. Then iterate over all stored logs and compare the sliced timestamp against the sliced start and end query values. If it falls within the bounds, include the log ID in the result.
- Since the timestamps have fixed width with leading zeros, slicing and lexicographical comparisons are both valid and simple.

#1138 Alphabet Board Path [Medium]

Key Insights

- Determine the row and column for each letter (using integer division and modulus).
- Because "z" is in a special row that only contains one column, the move order is critical to avoid invalid positions.
- For target letter "z", perform horizontal moves before vertical moves; for all other letters, do vertical moves before horizontal moves.
- Build the answer step-by-step by moving from your current position to each target letter.

Space & Time

Time Complexity: $O(N)$ where N is the length of target (each move is processed in constant time)

Space Complexity: $O(N)$ for the resulting string of moves

Solution

The approach calculates the destination coordinates for each character. For each letter in the target:

- Convert the letter to its board coordinates (row and col). For example, for letter c, $row = (ord(c) - ord('a')) // 5$ and $col = (ord(c) - ord('a')) \% 5$. Note that "z" (the 26th letter) always maps to (5, 0).
- To move from the current position (curRow, curCol) to the target's (targetRow, targetCol), decide on the order of moves: If the target letter is "z", first

move horizontally (left or right) then vertically (up or down) to avoid stepping into invalid regions from the extra row. For any other letter, move vertically (up or down) first, then horizontally (left or right). – Append "!" to the moves after reaching each letter. – Update the current position to the letter's coordinates.

This method ensures you only traverse valid cells on the board and minimizes moves by taking the optimal coordinate difference each step.

#3

MEDIUM

Longest Substring Without Repeating Characters

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Lists: Grind 169

Problem:

Given a string *s*, find the length of the longest substring without duplicate characters.

Example 1:

Input: *s* = "abcabcbb"

Output: 3

Explanation: The answer is "abc", with the length of 3. Note that "bca" and "cab" are also correct answers.

Example 2:

Input: *s* = "bbbbbb"

Output: 1

Explanation: The answer is "b", with the length of 1.

Example 3:

Input: *s* = "pwwkew"

Output: 3

Explanation: The answer is "wke", with the length of 3.

Notice that the answer must be a substring, "pwke" is a subsequence and not a substring.

Constraints:

- $0 \leq s.length \leq 5 * 10^4$
- *s* consists of English letters, digits, symbols and spaces.

MEDIUM

Longest Substring with At Most Two Distinct Characters

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Lists: Premium 98

Problem:

Given a string *s*, return the length of the longest substring that contains at most two distinct characters.

Example 1:

Input: *s* = "eceba"

Output: 3

Explanation: The substring is "ece" which its length is 3.

Example 2:

Input: *s* = "ccaabbb"

Output: 5

Explanation: The substring is "aabbb" which its length is 5.

Constraints:

- $1 \leq s.length \leq 105$
- *s* consists of English letters.

MEDIUM

Longest Substring with At Most K Distinct Characters

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Lists: Premium 98

Problem:

Given a string s and an integer k , return the length of the longest substring of s that contains at most k distinct characters.

Example 1:

Input: $s = \text{"eacea"}$, $k = 2$

Output: 3

Explanation: The substring is "eae" with length 3.

Example 2:

Input: $s = \text{"aa"}$, $k = 1$

Output: 2

Explanation: The substring is "aa" with length 2.

Constraints:

- $1 \leq s.length \leq 5 \times 10^4$
- $0 \leq k \leq 50$

MEDIUM

Longest Repeating Character Replacement

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Lists: Grind 169

Problem:

You are given a string *s* and an integer *k*. You can choose any character of the string and change it to any other uppercase English character. You can perform this operation at most *k* times.

Return the length of the longest substring containing the same letter you can get after performing the above operations.

Example 1:

Input: s = "ABAB", k = 2

Output: 4

Explanation: Replace the two 'A's with two 'B's or vice versa.

Example 2:

Input: s = "AABABBA", k = 1

Output: 4

Explanation: Replace the one 'A' in the middle with 'B' and form "AABBBBA".

The substring "BBBB" has the longest repeating letters, which is 4.

There may exist other ways to achieve this answer too.

Constraints:

- $1 \leq s.length \leq 105$
- s consists of only uppercase English letters.
- $0 \leq k \leq s.length$

Python

Find All Anagrams in a String

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Problem:

Given two strings *s* and *p*, return an array of all the start indices of *p*'s anagrams in *s*. You may return the answer in any order.

Example 1:

Input: *s* = "cbaebabacd", *p* = "abc"

Output: [0,6]

Explanation:

The substring with start index = 0 is "cba", which is an anagram of "abc".

The substring with start index = 6 is "bac", which is an anagram of "abc".

Example 2:

Input: *s* = "abab", *p* = "ab"

Output: [0,1,2]

Explanation:

The substring with start index = 0 is "ab", which is an anagram of "ab".

The substring with start index = 1 is "ba", which is an anagram of "ab".

The substring with start index = 2 is "ab", which is an anagram of "ab".

Constraints:

- $1 \leq s.length, p.length \leq 3 * 10^4$
- *s* and *p* consist of lowercase English letters.

#487

MEDIUM

Max Consecutive Ones II

Problem:

Given a binary array `nums`, return the maximum number of consecutive 1's in the array if you can flip at most one 0.

Example 1:

Input: `nums = [1,0,1,1,0]`

Output: 4

Explanation:

- If we flip the first zero, `nums` becomes `[1,1,1,1,0]` and we have 4 consecutive ones.
 - If we flip the second zero, `nums` becomes `[1,0,1,1,1]` and we have 3 consecutive ones.
- The max number of consecutive ones is 4.

Example 2:

Input: `nums = [1,0,1,1,0,1]`

Output: 4

Explanation:

- If we flip the first zero, `nums` becomes `[1,1,1,1,0,1]` and we have 4 consecutive ones.
 - If we flip the second zero, `nums` becomes `[1,0,1,1,1,1]` and we have 4 consecutive ones.
- The max number of consecutive ones is 4.

Constraints:

- $1 \leq \text{nums.length} \leq 105$
- `nums[i]` is either 0 or 1.

Follow up: What if the input numbers come in one by one as an infinite stream? In other words, you can't store all numbers coming from the stream as it's too large to hold in memory. Could you solve it efficiently?

Find K-Length Substrings with No Repeated Characters

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Lists: Premium 98

Problem:

Given a string s and an integer k , return the number of substrings in s of length k with no repeated characters.

Example 1:

Input: $s = \text{"havefunonleetcode"}, k = 5$

Output: 6

Explanation: There are 6 substrings they are:

'havef', 'avefu', 'vefun', 'efuno', 'etcod', 'tcode'.

Example 2:

Input: $s = \text{"home"}, k = 5$

Output: 0

Explanation: Notice k can be larger than the length of s . In this case, it is not possible to find any substring.

Constraints:

- $1 \leq s.length \leq 104$
- s consists of lowercase English letters.
- $1 \leq k \leq 104$

Python

Python

```

def numKLenSubstrNoRepeats(s: str, k: int) -> int:

Count Number of Nice Subarrays

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Math](#) · [Sliding Window](#) · [Prefix Sum](#)

Lists: [CodeSignal](#)

Problem:

Given an array of integers `nums` and an integer `k`. A continuous subarray is called nice if there are `k` odd numbers on it.

Return the number of nice sub-arrays.

Example 1:

Input: `nums = [1,1,2,1,1]`, `k = 3`

Output: 2

Explanation: The only sub-arrays with 3 odd numbers are `[1,1,2,1]` and `[1,2,1,1]`.

Example 2:

Input: `nums = [2,4,6]`, `k = 1`

Output: 0

Explanation: There are no odd numbers in the array.

Example 3:

Input: `nums = [2,2,2,1,2,2,1,2,2,2]`, `k = 2`

Output: 16

Constraints:

- `1 <= nums.length <= 50000`
- `1 <= nums[i] <= 10^5`
- `1 <= k <= nums.length`

[*] Sliding Window — Pattern Solution (stored optimal)

Python

```

# Python solution with line-by-line comments

def numberOfSubarrays(nums, k):
    # Initialize dictionary to store frequency of prefix sums
    prefix_count = {0: 1} # There is one way to have zero odd numbers initially.
    count = 0 # This will store the final count of nice subarrays
    odd_sum = 0 # Prefix sum representing the count of odd numbers so far

    # Iterate through each number in the array
    for num in nums:
        # If the number is odd, increment the odd_count prefix sum
        if num % 2 == 1:
            odd_sum += 1

        # If there is a prefix such that (current odd_sum - prefix) equals k,
        # then we found subarrays ending here with k odd numbers
        count += prefix_count.get(odd_sum - k, 0)

        # Update the frequency for the current odd_sum in the hash table
        prefix_count[odd_sum] = prefix_count.get(odd_sum, 0) + 1

    # Return the total number of nice subarrays
    return count

# Example usage:

# nums = [1,1,2,1,1]
# k = 3
# print(numberOfSubarrays(nums, k)) # Expected output is 2

```

C++

```

// C++ solution with line-by-line comments
#include <vector>
#include <unordered_map>
using namespace std;

class Solution {
public:
    int numberOfSubarrays(vector<int>& nums, int k) {
        // Hash table to store prefix sum frequencies
        unordered_map<int, int> prefixCount;
        // There is one occurrence of a prefix sum of 0 initially
        prefixCount[0] = 1;

        int count = 0; // Total count of nice subarrays
        int oddSum = 0; // Current count of odd numbers

        // Iterate over each number in the array
        for (int num : nums) {
            // If the number is odd, increment the odd count
            if (num % 2 == 1)
                oddSum++;

            // If a prefix sum of (oddSum - k) exists, add its frequency to the count
            if (prefixCount.find(oddSum - k) != prefixCount.end())
                count += prefixCount[oddSum - k];
        }
    }
};

```

```

        // Increment frequency of the current oddSum in the hash table
        prefixCount[oddSum]++;
    }
    // Return the total number of nice subarrays
    return count;
}
};

HARD

Minimum Window Substring

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sliding Window](#)

Lists: Grind 169

Problem:

Given two strings s and t of lengths m and n respectively, return the minimum window substring of s such that every character in t (including duplicates) is included in the window. If there is no such substring, return the empty string `""`.

The testcases will be generated such that the answer is unique.

Example 1:

Input: $s = \text{"ADOBECODEBANC"}, t = \text{"ABC"}$

Output: `"BANC"`

Explanation: The minimum window substring `"BANC"` includes 'A', 'B', and 'C' from string t .

Example 2:

Input: $s = \text{"a"}, t = \text{"a"}$

Output: `"a"`

Explanation: The entire string s is the minimum window.

Example 3:

Input: $s = \text{"a"}, t = \text{"aa"}$

Output: `""`

Explanation: Both 'a's from t must be included in the window.

Since the largest window of s only has one 'a', return empty string.

Constraints:

- $m == s.length$
- $n == t.length$
- $1 \leq m, n \leq 105$
- s and t consist of uppercase and lowercase English letters.

Follow up: Could you find an algorithm that runs in $O(m + n)$ time?

}

```

Quick Review — Sliding Window 9 questions · insights · complexity · solution

#3 Longest Substring Without Repeating Characters [Medium]

Key Insights

- Use the sliding window technique to maintain a window of unique characters.
- Use a hash table (or dictionary) to quickly check for duplicate characters and update window boundaries.
- The window is expanded by moving a pointer (right) and contracted by moving another pointer (left) when duplicates are encountered.
- Time complexity can be maintained at $O(n)$ by ensuring each character is processed a limited number of times.

Space & Time

Time Complexity: $O(n)$, where n is the length of the input string.

Space Complexity: $O(\min(n, m))$, where m is the size of the character set (constant for fixed character sets).

Solution

The solution uses a sliding window technique with two pointers, left and right, to keep track of the current substring without repeating characters. A hash table (dictionary or map) is used to store the most recent index of each character encountered. As the right pointer moves forward, if a duplicate character is found within the current window, the left pointer is advanced to the position right after where the duplicate was last seen. This ensures that the window always contains unique characters. The maximum length is updated throughout the process.

#159 Longest Substring with At Most Two Distinct Characters [Medium]

Key Insights

- Use a sliding window to maintain a contiguous substring.
- Keep track of character frequencies within the current window using a hash map or dictionary.
- When the window contains more than two distinct characters, shrink the window from the left until only two remain.
- Update the maximum length each time the window satisfies the condition.

Space & Time

Time Complexity: $O(n)$ where n is the length of the string, since each character is processed at most twice.

Space Complexity: $O(1)$ because the hash map holds at most 3 entries (usually up to 2 distinct characters).

Solution

We use the sliding window technique with two pointers (left and right) to represent the current window. A hash table/dictionary records the count of each character inside the window. As we extend the right pointer, we update the count. If the hash table contains more than two distinct characters, we start moving the left pointer to reduce the number of distinct characters until we have at most two distinct keys. The length of the current valid window is then used to update our maximum length answer.

#340 Longest Substring with At Most K Distinct Characters [Medium]

Key Insights

- Use the sliding window technique to efficiently scan through the string.
- Maintain a hash table (or dictionary) that keeps track of the frequency of characters in the current window.
- When the number of distinct characters exceeds k , increment the left pointer to shrink the window until the condition is met.
- Update the maximum length of valid substrings throughout the process.

Space & Time

Time Complexity: $O(n)$, where n is the length of the string, as each character is processed at most twice (once when expanding the window and once when contracting it).

Space Complexity: $O(\min(m, k))$, where m is the size of the charset (or number of unique characters in s), since at most $k+1$ keys are stored.

Solution

This problem is solved using the sliding window technique. The algorithm keeps track of a window defined by two indices (left and right pointers). A hash map is used to count the frequency of each character in the current window. As the right pointer extends the window, the count of the character is incremented. When the count of distinct keys in the map exceeds k , the left pointer is moved forward while decrementing the count of the leftmost character, until the condition is restored. The maximum window length encountered is recorded and returned as the result.

#424 Longest Repeating Character Replacement [Medium]

Key Insights

- Use a Sliding Window algorithm to keep track of a contiguous substring.
- Maintain a frequency count of letters in the current window.
- Keep track of the count of the most frequent character in the window.
- If the current window size minus the maximum frequency is greater than k , shrink the window.
- The maximum window size seen during the process is the answer.

Space & Time

Time Complexity: $O(n)$ where n is the length of the string, since the window traverses the string in linear time.

Space Complexity: $O(1)$ because the frequency count for letters (A–Z) has a constant size.

Solution

The problem is solved using the sliding window technique. We initialize two pointers representing the left and right bounds of the current window. As we expand the window by moving the right pointer, we update the frequency count of the letter at the right pointer and track the letter that appears most frequently. The key observation is that the number of characters that need to be replaced in the current window is the window's size minus the count of the most frequently occurring letter. If this number exceeds k , we increment the left pointer to shrink the window until the condition is satisfied again. The maximum size of the window during the process gives the answer.

#438 Find All Anagrams in a String [Medium]

Key Insights

- Use a sliding window of length equal to p over s .
- Maintain frequency counts of characters in p and within the current window in s .
- Compare frequency counts to determine if the current window is an anagram.
- Update the window efficiently by adding one character and removing the character that goes out of the window.

Space & Time

Time Complexity: $O(n)$ where n is the length of s .

Space Complexity: $O(1)$ since we use fixed-size frequency arrays or hash maps.

Solution

We use the sliding window technique to iterate over s with a window size equal to the length of p . First, count the frequencies of characters in p . Then, iterate over s and update a frequency count for the current window. When the window size equals the length of p , compare the two frequency counts. If they match, record the start index. To slide the window efficiently, increment the count for the incoming character and decrement the count for the outgoing character. This way, we achieve an $O(n)$ solution that is optimal for the problem constraints.

#487 Max Consecutive Ones II [Medium]

Key Insights

- Utilize a sliding window to maintain the current segment.

- The window can contain at most one 0.
- Expand the window with the right pointer and contract it with the left pointer when the constraint is violated.
- The maximum window size observed during this process is the desired result.

Space & Time

Time Complexity: $O(n)$ where n is the number of elements in the array.

Space Complexity: $O(1)$.

Solution

We use a sliding window approach to efficiently find the longest contiguous subarray that contains at most one 0. Two pointers (left and right) define the window. As we iterate with the right pointer, counting zeros in the window, we adjust the left pointer when the count of zeros exceeds one. The length of the valid window gives us the number of consecutive 1's (considering one flipped 0), and we update the maximum length accordingly.

#1100 Find K-Length Substrings with No Repeated Characters [Medium]

Key Insights

- Use a sliding window of fixed size k .
- Track character counts within the current window using a hash table (or frequency array).
- When a duplicate is found in the window, slide the window from the left to remove duplicates.
- Count a valid window when its size equals k and all characters are unique.
- Optimize by adjusting the window immediately after counting a valid substring.

Space & Time

Time Complexity: $O(n)$ where n is the length of s , as each character is visited at most twice.

Space Complexity: $O(1)$ since the frequency tracking is over a fixed set (26 lowercase letters).

Solution

We use a sliding window approach with two pointers: left and right. A hash table (or frequency array) tracks the occurrences of characters in the window. As we move the right pointer, we update the frequency and check for duplicates. If a duplicate is encountered, we increment the left pointer until the duplicate is removed. Once the window size exactly equals k , we have a valid substring, so we increment our count and then slide the window forward. This ensures that every possible k -length substring is examined once.

#1248 Count Number of Nice Subarrays [Medium]

Key Insights

- Convert the problem to counting subarrays with a specific "prefix sum" value where the sum represents the count of odd numbers.
- Use a hash table (or dictionary) to store the frequency of prefix sums encountered.
- The number of nice subarrays ending at the current index equals the frequency of (current prefix sum - k) seen so far.
- This approach allows you to find the answer in one pass over the array.

Space & Time

Time Complexity: $O(n)$, where n is the number of elements in $nums$, because we traverse the array once.

Space Complexity: $O(n)$, in the worst case where each prefix sum is unique and stored in the hash table.

Solution

We solve the problem using a prefix sum approach. First, we iterate through the array and convert it into a prefix sum representing the cumulative count of odd numbers encountered. As we compute the prefix sums, we use a hash table to record how many times each prefix sum appears. For every current prefix sum value, we check how many times we have seen a prefix sum equal to (current prefix sum - k). The idea is that if $\text{prefix}[j] - \text{prefix}[i]$ equals k , then between indices $i+1$ and j , there are exactly k odd numbers. This gives us the count of valid subarrays ending at the current index.

This method works efficiently as it requires only a single pass through the array and maintains a running frequency count using the hash table.

#76 Minimum Window Substring [Hard]

Key Insights

- Use a sliding window approach to dynamically adjust the window boundaries.
- Utilize a hash table (or dictionary) to keep track of the frequency of characters required (from t) and the frequency within the current window.
- Expand the window until it satisfies the requirements, then contract to minimize the window.
- Efficiently update counts and check valid window with two pointers (left and right).

Space & Time

Time Complexity: $O(m + n)$, where m is the length of s and n is the length of t .

Space Complexity: $O(m + n)$ in the worst case due to the storage for the hash maps.

Solution

We use a sliding window technique with two pointers representing the window's boundaries. First, create a frequency map of characters from t . Then, expand the right pointer to include characters in the window until the window contains all required characters (meeting or exceeding the counts in t). Once the requirement is met, try contracting the window by moving the left pointer to reduce its size while still maintaining a valid window. Throughout the process, if a valid window is found that is smaller than the previously recorded minimum window, update the minimum. The solution leans heavily on hash tables to track counts and compares them against the required counts from t .

#6 Sorting — 9 questions · #6 of 21

#169

EASY

Majority Element

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Divide and Conquer](#) · [Sorting](#) · [Counting](#)

Lists: Grind 169

Problem:

Given an array `nums` of size `n`, return the majority element.

The majority element is the element that appears more than $n / 2$ times. You may assume that the majority element always exists in the array.

Example 1:

Input: `nums = [3,2,3]`

Output: 3

Example 2:

Input: `nums = [2,2,1,1,1,2,2]`

Output: 2

Constraints:

- `n == nums.length`
- `1 <= n <= 5 * 104`
- `-109 <= nums[i] <= 109`
- The input is generated such that a majority element will exist in the array.

Follow-up: Could you solve the problem in linear time and in $O(1)$ space?

```

[*] Sorting — Pattern Solution (stored optimal)

Python

```
# Python implementation of the Boyer-Moore Voting Algorithm

def majorityElement(nums):
    # Initialize candidate and counter
    candidate = None
    count = 0

    # Iterate over each number in the input list
    for num in nums:
        # If count is 0, choose the current number as the candidate
        if count == 0:
            candidate = num
        # Increment count if the current number equals the candidate, otherwise decrement
        count += 1 if num == candidate else -1
    # Return the candidate, which is the majority element
    return candidate

# Example usage
print(majorityElement([2,2,1,1,1,2,2])) # Output: 2
```

C++

```
// C++ implementation of the Boyer-Moore Voting Algorithm

#include <vector>
using namespace std;

class Solution {
public:
    int majorityElement(vector<int>& nums) {
        // Candidate for the majority element
        int candidate = 0;
        // Counter for the candidate occurrences
        int count = 0;

        // Iterate through each number in the vector
        for (int num : nums) {
            // If counter drops to 0, set candidate to current number
            if (count == 0) {
                candidate = num;
            }
            // Increment counter if current number equals candidate; otherwise, decrement
            count += (num == candidate) ? 1 : -1;
        }
        // Candidate is guaranteed to be the majority element
        return candidate;
    }
};

// Example usage
// int main() {
//     vector<int> nums = {2,2,1,1,1,2,2};
//     Solution sol;
//     int result = sol.majorityElement(nums); // result will be 2
//     return 0;
// }
```

EASY

Contains Duplicate

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Hash Table](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given an integer array `nums`, return `true` if any value appears at least twice in the array, and return `false` if every element is distinct.

Example 1:

Input: `nums = [1,2,3,1]`

Output: `true`

Explanation:

The element 1 occurs at the indices 0 and 3.

Example 2:

Input: `nums = [1,2,3,4]`

Output: `false`

Explanation:

All elements are distinct.

Example 3:

Input: `nums = [1,1,1,3,3,4,3,2,4,2]`

Output: `true`

Constraints:

- `1 <= nums.length <= 105`
- `-109 <= nums[i] <= 109`

Valid Anagram

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given two strings *s* and *t*, return true if *t* is an anagram of *s*, and false otherwise.

Example 1:

Input: *s* = "anagram", *t* = "nagaram"

Output: true

Example 2:

Input: *s* = "rat", *t* = "car"

Output: false

Constraints:

- $1 \leq s.length, t.length \leq 5 * 10^4$
- *s* and *t* consist of lowercase English letters.

Follow up: What if the inputs contain Unicode characters? How would you adapt your solution to such a case?

Meeting Rooms

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Sorting](#)

Lists: Grind 169 | Premium 98

Problem:

Given an array of meeting time intervals where $\text{intervals}[i] = [\text{start}_i, \text{end}_i]$, determine if a person could attend all meetings.

Example 1:

Input: $\text{intervals} = [[0,30],[5,10],[15,20]]$
 Output: false

Example 2:

Input: $\text{intervals} = [[7,10],[2,4]]$
 Output: true

Constraints:

- $0 \leq \text{intervals.length} \leq 104$
- $\text{intervals}[i].\text{length} == 2$
- $0 \leq \text{start}_i < \text{end}_i \leq 106$

Largest Unique Number

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Sorting](#)

Lists: Premium 98

Problem:

Given a list of the scores of different students, items, where items[i] = [IDi, scorei] represents one score from a student with IDi, calculate each student's top five average.

Return the answer as an array of pairs result, where result[j] = [IDj, topFiveAveragej] represents the student with IDj and their top five average. Sort result by IDj in increasing order.

A student's top five average is calculated by taking the sum of their top five scores and dividing it by 5 using integer division.

Example 1:

Input: items =

[[1,91],[1,92],[2,93],[2,97],[1,60],[2,77],[1,65],[1,87],[1,100],[2,100],[2,76]]

Output: [[1,87],[2,88]]

Explanation:

The student with ID = 1 got scores 91, 92, 60, 65, 87, and 100. Their top five average is $(100 + 92 + 91 + 87 + 65) / 5 = 87$.

The student with ID = 2 got scores 93, 97, 77, 100, and 76. Their top five average is $(100 + 97 + 93 + 77 + 76) / 5 = 88.6$, but with integer division their average converts to 88.

Example 2:

Input: items =

[[1,100],[7,100],[1,100],[7,100],[1,100],[7,100],[1,100],[7,100],[1,100],[7,100]]

Output: [[1,100],[7,100]]

Constraints:

- $1 \leq \text{items.length} \leq 1000$
- $\text{items}[i].\text{length} == 2$
- $1 \leq \text{ID}_i \leq 1000$
- $0 \leq \text{score}_i \leq 100$
- For each ID_i, there will be at least five scores.

Relative Sort Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Sorting](#) · [Counting Sort](#)

Lists: Denny Zhang

Problem:

Given two arrays arr1 and arr2, the elements of arr2 are distinct, and all elements in arr2 are also in arr1.

Sort the elements of arr1 such that the relative ordering of items in arr1 are the same as in arr2. Elements that do not appear in arr2 should be placed at the end of arr1 in ascending order.

Example 1:

```
Input: arr1 = [2,3,1,3,2,4,6,7,9,2,19], arr2 = [2,1,4,3,9,6]
Output: [2,2,2,1,4,3,3,9,6,7,19]
```

Example 2:

Input: arr1 = [28,6,22,8,44,17], arr2 = [22,28,8,6]
Output: [22,28,8,6,17,44]

Constraints:

- $1 \leq \text{arr1.length}, \text{arr2.length} \leq 1000$
- $0 \leq \text{arr1}[i], \text{arr2}[i] \leq 1000$
- All the elements of arr2 are distinct.
- Each arr2[i] is in arr1.

[*] Sorting — Pattern Solution (matched from community answers)

Python

```

# Python solution using a frequency dictionary

def relativeSortArray(arr1, arr2):
    # Count frequency of each element in arr1
    count = {}
    for num in arr1:
        count[num] = count.get(num, 0) + 1

    result = []
    # Process elements defined in arr2: append each element count times
    for num in arr2:
        if num in count:
            result.extend([num] * count[num])
            # Remove the element from the count dictionary
            del count[num]

    # Process remaining numbers: sort them in ascending order and append
    remaining = []
    for num, freq in count.items():
        remaining.extend([num] * freq)
    result.extend(sorted(remaining))

    return result

# Example usage:

print(relativeSortArray([2,3,1,3,2,4,6,7,9,2,19], [2,1,4,3,9,6]))

```

MEDIUM

Group Anagrams

Problem:

Given an array of strings `strs`, group the anagrams together. You can return the answer in any order.

Example 1:

Input: `strs = ["eat","tea","tan","ate","nat","bat"]`

Output: `[["bat"],["nat","tan"],["ate","eat","tea"]]`

Explanation:

- There is no string in `strs` that can be rearranged to form "bat".
- The strings "nat" and "tan" are anagrams as they can be rearranged to form each other.
- The strings "ate", "eat", and "tea" are anagrams as they can be rearranged to form each other.

Example 2:

Input: `strs = [""]`

Output: `[[""]]`

Example 3:

Input: `strs = ["a"]`

Output: `[["a"]]`

Constraints:

- $1 \leq \text{strs.length} \leq 104$
- $0 \leq \text{strs}[i].\text{length} \leq 100$
- `strs[i]` consists of lowercase English letters.

>> Brute Force [Sorting] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def groupAnagrams(self, strs):
        # Brute Force  $O(n^2 \cdot k \log k)$  — compare each pair by sorting
        n = len(strs)
        used = [False] * n
        result = []
        for i in range(n):
            if used[i]: continue
            group = [strs[i]]
            used[i] = True
            for j in range(i + 1, n):
                if not used[j] and sorted(strs[i]) == sorted(strs[j]):
                    group.append(strs[j])
                    used[j] = True
            result.append(group)
        return result
```

Python

Python

```
# Python solution for grouping anagrams
from collections import defaultdict

def groupAnagrams(strs):
    # Create a dictionary to hold lists of anagrams; default to an empty list for new keys
    anagrams = defaultdict(list)
    # Iterate over each string in the input list
    for s in strs:
        # Sort the string to use as a key; sorted returns a list so join back to string
        key = ''.join(sorted(s))
        # Append the original string under the sorted key
        anagrams[key].append(s)
    # Return the grouped anagrams as a list of lists
    return list(anagrams.values())

# Example usage:
if __name__ == "__main__":
    strs = ["eat", "tea", "tan", "ate", "nat", "bat"]
    result = groupAnagrams(strs)
    print(result)
```

Python

```
class Solution:
    def groupAnagrams(self, strs: List[str]) -> List[List[str]]:
        dict = collections.defaultdict(list)

        for str in strs:
            key = ''.join(sorted(str))
            dict[key].append(str)

        return dict.values()

Merge Intervals

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given an array of intervals where $\text{intervals}[i] = [\text{start}_i, \text{end}_i]$, merge all overlapping intervals, and return an array of the non-overlapping intervals that cover all the intervals in the input.

Example 1:

Input: $\text{intervals} = [[1,3],[2,6],[8,10],[15,18]]$

Output: $[[1,6],[8,10],[15,18]]$

Explanation: Since intervals $[1,3]$ and $[2,6]$ overlap, merge them into $[1,6]$.

Example 2:

Input: $\text{intervals} = [[1,4],[4,5]]$

Output: $[[1,5]]$

Explanation: Intervals $[1,4]$ and $[4,5]$ are considered overlapping.

Example 3:

Input: $\text{intervals} = [[4,7],[1,4]]$

Output: $[[1,7]]$

Explanation: Intervals $[1,4]$ and $[4,7]$ are considered overlapping.

Constraints:

- $1 \leq \text{intervals.length} \leq 104$
- $\text{intervals}[i].\text{length} == 2$
- $0 \leq \text{start}_i \leq \text{end}_i \leq 104$

Analyze User Website Visit Pattern

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Sorting](#)

Lists: Premium 98

Problem:

You are given two string arrays `username` and `website` and an integer array `timestamp`. All the given arrays are of the same length and the tuple `[username[i], website[i], timestamp[i]]` indicates that the user `username[i]` visited the website `website[i]` at time `timestamp[i]`.

A pattern is a list of three websites (not necessarily distinct).

- For example, `["home", "away", "love"]`, `["leetcode", "love", "leetcode"]`, and `["luffy", "luffy", "luffy"]` are all patterns.

The score of a pattern is the number of users that visited all the websites in the pattern in the same order they appeared in the pattern.

- For example, if the pattern is `["home", "away", "love"]`, the score is the number of users `x` such that `x` visited "home" then visited "away" and visited "love" after that.
- Similarly, if the pattern is `["leetcode", "love", "leetcode"]`, the score is the number of users `x` such that `x` visited "leetcode" then visited "love" and visited "leetcode" one more time after that.
- Also, if the pattern is `["luffy", "luffy", "luffy"]`, the score is the number of users `x` such that `x` visited "luffy" three different times at different timestamps.

Return the pattern with the largest score. If there is more than one pattern with the same largest score, return the lexicographically smallest such pattern.

Note that the websites in a pattern do not need to be visited contiguously, they only need to be visited in the order they appeared in the pattern.

Example 1:

Input: `username = ["joe","joe","joe","james","james","james","james","mary","mary","mary"]`,
`timestamp = [1,2,3,4,5,6,7,8,9,10]`, `website =`
`["home","about","career","home","cart","maps","home","home","about","career"]`
Output: `["home","about","career"]`

Explanation: The tuples in this example are:

`[["joe", "home", 1], ["joe", "about", 2], ["joe", "career", 3], ["james", "home", 4], ["james", "cart", 5], ["james", "maps", 6], ["james", "home", 7], ["mary", "home", 8], ["mary", "about", 9], and`

```
["mary","career",10].
```

The pattern ("home", "about", "career") has score 2 (joe and mary).

The pattern ("home", "cart", "maps") has score 1 (james).

The pattern ("home", "cart", "home") has score 1 (james).

The pattern ("home", "maps", "home") has score 1 (james).

The pattern ("cart", "maps", "home") has score 1 (james).

The pattern ("home", "home", "home") has score 0 (no user visited home 3 times).

Example 2:

Input: username = ["ua","ua","ua","ub","ub","ub"], timestamp = [1,2,3,4,5,6], website = ["a","b","a","a","b","c"]

Output: ["a","b","a"]

Constraints:

- $3 \leq \text{username.length} \leq 50$
- $1 \leq \text{username}[i].\text{length} \leq 10$
- $\text{timestamp.length} == \text{username.length}$
- $1 \leq \text{timestamp}[i] \leq 109$
- $\text{website.length} == \text{username.length}$
- $1 \leq \text{website}[i].\text{length} \leq 10$
- $\text{username}[i]$ and $\text{website}[i]$ consist of lowercase English letters.
- It is guaranteed that there is at least one user who visited at least three websites.
- All the tuples $[\text{username}[i], \text{timestamp}[i], \text{website}[i]]$ are unique.

))

```

Quick Review — Sorting 9 questions · insights · complexity · solution

#169 Majority Element [Easy]

Key Insights

- The majority element appears more than half the length of the array.
- A simple hash table approach can count occurrences, but a more efficient solution exists.
- The Boyer–Moore Voting Algorithm finds the majority in $O(n)$ time and $O(1)$ space.
- The algorithm maintains a candidate and a counter, adjusting the candidate when the count drops to zero.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

We use the Boyer–Moore Voting Algorithm to identify the majority element. The algorithm iterates through the array using two variables: one for the candidate and one for the count. Initially, we set the candidate to an arbitrary value and count to 0. For each element, if the count is 0, we update the candidate to the current element. Then, if the current element is the same as the candidate, we increment the count; otherwise, we decrement it. Since the majority element appears more than $n/2$ times, it will remain as the candidate by the end of the iteration.

#217 Contains Duplicate [Easy]

Key Insights

- A hash set can be used to keep track of seen numbers.
- Iterating once through the array provides an efficient solution.
- If a number is already in the set, a duplicate is found.
- Alternative approaches like sorting have a higher time complexity ($O(n \log n)$).

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(n)$

Solution

The solution uses a hash set to track the numbers seen while iterating through the array. For each number in the array:

– Check if it exists in the hash set. – If it does, return true immediately as a duplicate is found. – Otherwise, add the number to the hash set. If the iteration completes without finding any duplicates, return false. This approach efficiently determines if any duplicates exist in a single pass.

#242 Valid Anagram [Easy]

Key Insights

- If s and t have different lengths, they cannot be anagrams.
- An anagram requires exactly the same character frequency for both strings.
- Using a hash table (or frequency array when limited to 26 lowercase letters) provides an efficient solution.
- An alternative approach is to sort both strings and compare them.
- For Unicode inputs, a hash table is more adaptable than a fixed-size frequency array.

Space & Time

Time Complexity: $O(n)$, where n is the length of the strings (using a hash table for counting).

Space Complexity: $O(1)$ if we use a fixed-size array (for 26 letters), otherwise $O(n)$ for a hash table with a larger character set.

Solution

We use a hash table (dictionary) to count the frequency of each character in the first string s . Then, we iterate over string t and decrement the count for each character. If at any point a character count goes negative or a character is missing in the hash table, t cannot be an anagram of s . Finally, if all counts return to zero, the strings are anagrams. This approach is efficient and handles the problem in linear time.

#252 Meeting Rooms [Easy]

Key Insights

- Sort the intervals based on their starting times.
- Compare each interval's end time with the next interval's start time.
- Detect overlap if the end time of one meeting exceeds the start time of the following meeting.
- If no overlaps are detected, all meetings can be attended.

Space & Time

Time Complexity: $O(n \log n)$ due to sorting the intervals.

Space Complexity: $O(1)$ if sorting is done in-place; otherwise $O(n)$.

Solution

The solution starts by sorting the intervals in ascending order by their start times. After sorting, iterate through the intervals and for each consecutive pair, check if the previous meeting's end time exceeds the next meeting's start time. An overlap indicates that the person cannot attend all meetings. The primary data structure used is an array (or list) for holding the intervals. Sorting makes it easier to compare adjacent intervals for potential overlaps.

#1086 Largest Unique Number [Easy]

Key Insights

- Use a hash table (or dictionary) to count the frequency of each number.
- Iterate over the hash table to find the numbers that appear exactly once.
- Identify the maximum number among the unique numbers.
- Return -1 if no unique number exists.

Space & Time

Time Complexity: $O(n)$, where n is the number of elements in $nums$.

Space Complexity: $O(n)$, for the hash table storing frequency counts.

Solution

The approach starts by initializing a hash table to keep track of the frequency of each element in the array. Once the frequency count is complete, we traverse the hash table to collect numbers that appear exactly once. Finally, we determine the maximum number among these unique elements. If there is no unique element, we return -1 . This method is efficient because the frequency count and the search for the maximum unique element both run in linear time relative to the input size.

#1122 Relative Sort Array [Easy]

Key Insights

- Use a hash table (or array for counting given the value constraints) to count the occurrences of each element in $arr1$.
- Iterate through $arr2$ and for each element, append it to the result based on its count from the hash table.
- Remove the used elements from the hash table.
- Sort the remaining elements (those not in $arr2$) in ascending order and append them to the result.

Space & Time

Time Complexity: $O(n + m \log m)$ where n is the length of `arr1` and m is the number of leftover elements not in `arr2`. Given that element values are bounded (0 to 1000), a counting sort can make this nearly $O(n)$.

Space Complexity: $O(n)$ for storing the frequency counts and the result array.

Solution

The solution leverages a frequency counter (hash table) to count how many times each element appears in `arr1`. We then process `arr2` to add each number in its given order according to its frequency. Finally, we sort the remaining numbers that are not in `arr2` and append them to the result array. This approach ensures that the relative order specified by `arr2` is maintained and that the other elements are sorted in ascending order.

#49 Group Anagrams [Medium]

Key Insights

- Anagrams have the same characters when sorted alphabetically.
- Sorting each string provides a unique key for grouping.
- Use a hash table (dictionary) to map each sorted key to a list of its original strings.
- Finally, gather all the lists from the dictionary to form the result.

Space & Time

Time Complexity: $O(n * k \log k)$, where n is the number of strings and k is the maximum length of a string (due to sorting each string).

Space Complexity: $O(n * k)$ for storing the grouped strings in the hash table.

Solution

The primary idea is to iterate through each string, sort it to obtain a key that represents its character composition, and then group the original string under this key in a hash table. After processing all strings, the values of the hash table will be the groups of anagrams. This approach efficiently groups anagrams by leveraging sorting and a dictionary for constant-time lookups.

#56 Merge Intervals [Medium]

Key Insights

- Sort the intervals based on their start values.
- Use a pointer or iteration to compare the current interval with the last merged interval.
- If the current interval overlaps with the previous one, merge them by updating the end time.
- Otherwise, add the current interval to the results as a new merged interval.

Space & Time

Time Complexity: $O(n \log n)$ due to sorting the intervals.

Space Complexity: $O(n)$ to store the merged intervals.

Solution

First, sort the array of intervals based on the starting time. Then, iterate through the sorted list and check if the current interval overlaps with the last interval in the merged list. If an overlap is detected (i.e., the start of the current interval is less than or equal to the end of the last merged interval), update the last merged interval's end to be the maximum of both ends. If there is no overlap, simply add the current interval to the merged list. This approach efficiently merges overlapping intervals and ensures that all intervals are processed in a single pass after sorting.

#1152 Analyze User Website Visit Pattern [Medium]

Key Insights

- Combine the inputs into a single list of events and sort them by timestamp.
- Group the visits by each user, preserving the sorted order.
- Generate all unique combinations of 3-sequences for each user (order matters and non-contiguous visits are allowed).

- Use a dictionary (or hash map) to map each 3-sequence pattern to the set of users who visited that pattern.
- The problem constraints are small, so generating combinations per user (even using triple nested loops) is acceptable.
- When multiple patterns have the same frequency, choose the lexicographically smallest one.

Space & Time

Time Complexity: $O(U * L^3)$ where U is the number of users and L is the maximum length of visits per user (since we generate combinations of 3 visits per user). Sorting all events costs $O(N \log N)$ for N total events.

Space Complexity: $O(P)$ where P is the number of unique 3-sequence patterns stored in the dictionary, plus $O(N)$ for grouping the events.

Solution

– Aggregate the events by user while sorting them based on timestamp. – For each user, generate all sets of 3-website patterns (to avoid duplicate patterns per user). – Use a hash map to count the number of unique users for each pattern. – Traverse the map to find the pattern with the highest count. In case of a tie, compare patterns lexicographically. – Return the pattern that meets the criteria.

EASY

Add Binary

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Math](#) · [String](#) · [Bit Manipulation](#) · [Simulation](#)

Lists: Grind 169

Problem:

Given two binary strings *a* and *b*, return their sum as a binary string.

Example 1:

Input: *a* = "11", *b* = "1"

Output: "100"

Example 2:

Input: *a* = "1010", *b* = "1011"

Output: "10101"

Constraints:

- $1 \leq a.length, b.length \leq 104$
- *a* and *b* consist only of '0' or '1' characters.
- Each string does not contain leading zeros except for the zero itself.

Python

Python

```
# Function to add two binary strings
def addBinary(a: str, b: str) -> str:
    i = len(a) - 1 # Pointer for string a
    j = len(b) - 1 # Pointer for string b
    carry = 0 # Initialize carry to 0
    result = [] # List to store binary digits

    # Loop until both strings are processed and no carry remains
    while i >= 0 or j >= 0 or carry:
        total_sum = carry # Start with the carry from previous step

        if i >= 0: # If there is a digit left in a
            total_sum += int(a[i]) # Convert character to integer and add
            i -= 1 # Move to the next digit
        if j >= 0: # If there is a digit left in b
            total_sum += int(b[j]) # Convert character to integer and add
            j -= 1 # Move to the next digit

        # Append the remainder of total_sum divided by 2 (0 or 1)
        result.append(str(total_sum % 2))
        carry = total_sum // 2 # Update the carry

    # Reverse the result since we built it backwards and join to form a string
    return ''.join(result[::-1])
```

```

}
```

[*] Bit Manipulation — Pattern Solution (stored optimal)

Python

```
# Function to add two binary strings
def addBinary(a: str, b: str) -> str:
    i = len(a) - 1 # Pointer for string a
    j = len(b) - 1 # Pointer for string b
    carry = 0 # Initialize carry to 0
    result = [] # List to store binary digits

    # Loop until both strings are processed and no carry remains
    while i >= 0 or j >= 0 or carry:
        total_sum = carry # Start with the carry from previous step

        if i >= 0: # If there is a digit left in a
            total_sum += int(a[i]) # Convert character to integer and add
            i -= 1 # Move to the next digit
        if j >= 0: # If there is a digit left in b
            total_sum += int(b[j]) # Convert character to integer and add
            j -= 1 # Move to the next digit

        # Append the remainder of total_sum divided by 2 (0 or 1)
        result.append(str(total_sum % 2))
        carry = total_sum // 2 # Update the carry

    # Reverse the result since we built it backwards and join to form a string
    return ''.join(result[::-1])

# Sample test cases
print(addBinary("11", "1")) # Expected output: "100"
print(addBinary("1010", "1011")) # Expected output: "10101"
```

C++

```
// C++ solution for adding two binary strings
#include <iostream>
#include <string>
#include <algorithm>
using namespace std;

string addBinary(string a, string b) {
    int i = a.size() - 1; // Pointer for string a
    int j = b.size() - 1; // Pointer for string b
    int carry = 0; // Initialize the carry
    string result = ""; // String to store result in reverse order

    // Loop until both strings and the carry have been fully processed
    while (i >= 0 || j >= 0 || carry) {
        int totalSum = carry; // Start with the carry
        if (i >= 0) {
            totalSum += a[i] - '0'; // Convert char to integer and add
            i--; // Move left in string a
        }
        if (j >= 0) {
            totalSum += b[j] - '0'; // Convert char to integer and add
            j--; // Move left in string b
        }
        // Append the current bit to result (in reverse order)
        result.push_back((totalSum % 2) + '0');

        carry = totalSum / 2; // Calculate the new carry
    }

    // Reverse the result to correct the order of digits
    reverse(result.begin(), result.end());
    return result;
}

int main() {
    // Sample test cases
    cout << addBinary("11", "1") << endl; // Expected output: "100"
    cout << addBinary("1010", "1011") << endl; // Expected output: "10101"
    return 0;
}
```

EASY

Single Number

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Given a non-empty array of integers nums, every element appears twice except for one. Find that single one.

You must implement a solution with a linear runtime complexity and use only constant extra space.

Example 1:

Input: nums = [2,2,1]

Output: 1

Example 2:

Input: nums = [4,1,2,1,2]

Output: 4

Example 3:

Input: nums = [1]

Output: 1

Constraints:

- $1 \leq \text{nums.length} \leq 3 \cdot 10^4$
- $-3 \cdot 10^4 \leq \text{nums}[i] \leq 3 \cdot 10^4$
- Each element in the array appears twice except for one element which appears only once.

EASY

Reverse Bits

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Divide and Conquer](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Reverse bits of a given 32 bits signed integer.

Example 1:

Input: n = 43261596

Output: 964176192

Explanation:

Example 2:

Input: n = 2147483644

Output: 1073741822

Explanation:

Constraints:

- $0 \leq n \leq 2^{31} - 2$
- n is even.

Follow up: If this function is called many times, how would you optimize it?

Python

[Python](#)

```
# Function to reverse bits of a 32-bit binary string.
def reverse_bits(n: str) -> int:
    # Reverse the binary string using slicing.
    reversed_binary = n[::-1]
    # Convert the reversed binary string to an integer.
    result = int(reversed_binary, 2)
    return result

# Example usage:
binary_input = "00000010100101000001111010011100"
print(reverse_bits(binary_input)) # Expected output: 964176192

EASY

Number of 1 Bits

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Divide and Conquer](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Given a positive integer n , write a function that returns the number of set bits in its binary representation (also known as the Hamming weight).

Example 1:

Input: $n = 11$

Output: 3

Explanation:

The input binary string 1011 has a total of three set bits.

Example 2:

Input: $n = 128$

Output: 1

Explanation:

The input binary string 10000000 has a total of one set bit.

Example 3:

Input: $n = 2147483645$

Output: 30

Explanation:

The input binary string 111111111111111111111111111101 has a total of thirty set bits.

Constraints:

- $1 \leq n \leq 2^{31} - 1$

Follow up: If this function is called many times, how would you optimize it?

Python

Python

```
# Function to count the number of set bits in a given integer n
def hammingWeight(n: int) -> int:
    count = 0 # Initialize count of set bits
    while n:
        # Remove the lowest set bit from n
        n &= n - 1
        count += 1 # Increment count for each set bit removed
    return count

# Example usage:
print(hammingWeight(11)) # Output: 3
```

Python

```
class Solution:
    def hammingWeight(self, n: int) -> int:
        ans = 0

        for i in range(32):
            if (n >> i) & 1:
                ans += 1

        return ans
```

EASY

Missing Number

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Math](#) · [Binary Search](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Given an array `nums` containing n distinct numbers in the range $[0, n]$, return the only number in the range that is missing from the array.

Example 1:

Input: `nums = [3,0,1]`

Output: 2

Explanation:

$n = 3$ since there are 3 numbers, so all numbers are in the range $[0,3]$. 2 is the missing number in the range since it does not appear in `nums`.

Example 2:

Input: `nums = [0,1]`

Output: 2

Explanation:

$n = 2$ since there are 2 numbers, so all numbers are in the range $[0,2]$. 2 is the missing number in the range since it does not appear in `nums`.

Example 3:

Input: `nums = [9,6,4,2,3,5,7,0,1]`

Output: 8

Explanation:

$n = 9$ since there are 9 numbers, so all numbers are in the range $[0,9]$. 8 is the missing number in the range since it does not appear in `nums`.

Constraints:

- $n == \text{nums.length}$

- $1 \leq n \leq 104$
- $0 \leq \text{nums}[i] \leq n$
- All the numbers of nums are unique.

Follow up: Could you implement a solution using only $O(1)$ extra space complexity and $O(n)$ runtime complexity?

Python

```
# Brute Force Approach
class Solution:
    def missingNumber(self, nums):
        # Brute Force  $O(n^2)$  - for each  $0..n$  check if it's in nums
        for i in range(len(nums) + 1):
            if i not in nums:
                return i
```

Python

Python

```
# Function to find the missing number in the array
def missingNumber(nums):
    # Calculate n, where n is the length of the nums array
    n = len(nums)
    # Compute the expected total sum using the arithmetic sum formula for numbers 0 to n
    expected_sum = n * (n + 1) // 2
    # Compute the actual sum of the numbers in the array
    actual_sum = sum(nums)
    # The missing number is the difference between expected and actual sums
    return expected_sum - actual_sum

# Example Usage
print(missingNumber([3, 0, 1])) # Output: 2
```

Python

```
class Solution:
    def missingNumber(self, nums: list[int]) -> int:
        ans = len(nums)

Counting Bits

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Dynamic Programming](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Given an integer n , return an array `ans` of length $n + 1$ such that for each i ($0 \leq i \leq n$), `ans[i]` is the number of 1's in the binary representation of i .

Example 1:

Input: $n = 2$

Output: `[0,1,1]`

Explanation:

0 --> 0

1 --> 1

2 --> 10

Example 2:

Input: $n = 5$

Output: `[0,1,1,2,1,2]`

Explanation:

0 --> 0

1 --> 1

2 --> 10

3 --> 11

4 --> 100

5 --> 101

Constraints:

- $0 \leq n \leq 10^5$

Follow up:

- It is very easy to come up with a solution with a runtime of $O(n \log n)$. Can you do it in linear time $O(n)$ and possibly in a single pass?
- Can you do it without using any built-in function (i.e., like `__builtin_popcount` in C++)?

Subsets

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Backtracking](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Given an integer array `nums` of unique elements, return all possible subsets (the power set).

The solution set must not contain duplicate subsets. Return the solution in any order.

Example 1:

Input: `nums = [1,2,3]`

Output: `[[], [1], [2], [1,2], [3], [1,3], [2,3], [1,2,3]]`

Example 2:

Input: `nums = [0]`

Output: `[[], [0]]`

Constraints:

- `1 <= nums.length <= 10`
- `-10 <= nums[i] <= 10`
- All the numbers of `nums` are unique.

Subsets II

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Backtracking](#) · [Bit Manipulation](#)

Lists: Denny Zhang

Problem:

Given an integer array `nums` that may contain duplicates, return all possible subsets (the power set).

The solution set must not contain duplicate subsets. Return the solution in any order.

Example 1:

Input: `nums = [1,2,2]`

Output: `[[], [1], [1,2], [1,2,2], [2], [2,2]]`

Example 2:

Input: nums = [0]

Output: [[],[0]]

Constraints:

- $1 \leq \text{nums.length} \leq 10$
- $-10 \leq \text{nums}[i] \leq 10$

>> Brute Force [Bit Manipulation] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def subsetsWithDup(self, nums):
        # Brute Force  $O(2^n \cdot n \log n)$  – bitmask with deduplication via set
        result = set()
        nums.sort()
        for mask in range(1 << len(nums)):
            sub = tuple(nums[i] for i in range(len(nums)) if mask & (1 << i))
            result.add(sub)
        return [list(s) for s in result]
```

Python

Python

```
def subsetsWithDup(nums):
    # Sort the numbers to handle duplicates
    nums.sort()
    result = [] # To store all subsets
    subset = [] # Current subset being built

    def backtrack(start):
        # Append a copy of the current subset to the result
        result.append(list(subset))
        # Iterate over possible elements to include
        for i in range(start, len(nums)):
            # If the current element is a duplicate and not at the start of this loop, skip it
            if i > start and nums[i] == nums[i - 1]:
                continue
            # Include current element into the subset
            subset.append(nums[i])
            # Recurse with next start index
            backtrack(i + 1)
            # Backtrack and remove the last element added
            subset.pop()

    backtrack(0)
    return result

Find the Duplicate Number

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Binary Search](#) · [Bit Manipulation](#)

Lists: Grind 169

Problem:

Given an array of integers `nums` containing $n + 1$ integers where each integer is in the range $[1, n]$ inclusive.

There is only one repeated number in `nums`, return this repeated number.

You must solve the problem without modifying the array `nums` and using only constant extra space.

Example 1:

Input: `nums = [1,3,4,2,2]`

Output: 2

Example 2:

Input: `nums = [3,1,3,4,2]`

Output: 3

Example 3:

Input: `nums = [3,3,3,3,3]`

Output: 3

Constraints:

- $1 \leq n \leq 10^5$
- `nums.length == n + 1`

- $1 \leq \text{nums}[i] \leq n$
- All the integers in nums appear only once except for precisely one integer which appears two or more times.

Follow up:

- How can we prove that at least one duplicate number must exist in nums?
- Can you solve the problem in linear runtime complexity?

Python

```
# Brute Force Approach
class Solution:
    def findDuplicate(self, nums):
        # Brute Force  $O(n^2)$  - for each number count its occurrences
        for i in range(len(nums)):
            count = 0
            for j in range(len(nums)):
                if nums[j] == nums[i]:
                    count += 1
            if count > 1:
                return nums[i]
```

Python

Python

```
# Function to find the duplicate number using Floyd's Tortoise and Hare algorithm.
def findDuplicate(nums):
    # Phase 1: Find the intersection point inside the cycle.
    tortoise = nums[0] # Initialize tortoise pointer.
    hare = nums[0] # Initialize hare pointer.
    while True:
        tortoise = nums[tortoise] # Move tortoise one step.
        hare = nums[nums[hare]] # Move hare two steps.
        if tortoise == hare: # If pointers meet, cycle is detected.
            break

    # Phase 2: Find the entrance to the cycle.
    pointer = nums[0] # Initialize a new pointer from the start.
    while pointer != tortoise:
        pointer = nums[pointer] # Move pointer one step.
        tortoise = nums[tortoise] # Move tortoise one step.
    return pointer # The duplicate number.

# Example usage:
if __name__ == "__main__":
    sample = [1, 3, 4, 2, 2]
    print(findDuplicate(sample)) # Expected output: 2

Find Root of N-Ary Tree

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [Bit Manipulation](#) · [Tree](#) · [DFS](#)

Lists: Premium 98

Problem:

You are given all the nodes of an N-ary tree as an array of Node objects, where each node has a unique value.

Return the root of the N-ary tree.

Custom testing:

An N-ary tree can be serialized as represented in its level order traversal where each group of children is separated by the null value (see examples).

For example, the above tree is serialized as

[1,null,2,3,4,5,null,null,6,7,null,8,null,9,10,null,null,11,null,12,null,13,null,null,14].

The testing will be done in the following way:

1. The input data should be provided as a serialization of the tree.
2. The driver code will construct the tree from the serialized input data and put each Node object into an array in an arbitrary order.
3. The driver code will pass the array to findRoot, and your function should find and return the root Node object in the array.
4. The driver code will take the returned Node object and serialize it. If the serialized value and the input data are the same, the test passes.

Example 1:

Input: tree = [1,null,3,2,4,null,5,6]

Output: [1,null,3,2,4,null,5,6]

Explanation: The tree from the input data is shown above.

The driver code creates the tree and gives findRoot the Node objects in an arbitrary order. For example, the passed array could be [Node(5),Node(4),Node(3),Node(6),Node(2),Node(1)] or [Node(2),Node(6),Node(1),Node(3),Node(5),Node(4)].

The findRoot function should return the root Node(1), and the driver code will serialize it and compare with the input data.

The input data and serialized Node(1) are the same, so the test passes.

Example 2:

Input: tree =

[1,null,2,3,4,5,null,null,6,7,null,8,null,9,10,null,null,11,null,12,null,13,null,null,14]

Output:

[1,null,2,3,4,5,null,null,6,7,null,8,null,9,10,null,null,11,null,12,null,13,null,null,14]

Constraints:

- The total number of nodes is between [1, 5 * 10⁴].
- Each node has a unique value.

Follow up:

- Could you solve this problem in constant space complexity with a linear time algorithm?

Quick Review — Bit Manipulation 10 questions · insights · complexity · solution

#67 Add Binary [Easy]

Key Insights

- Simulate binary addition just like you add numbers digit by digit.
- Process the strings from right to left, handling the carry at each step.
- Use modulo and division operations to extract the current digit and update the carry.
- Append any remaining carry at the end.

Space & Time

Time Complexity: $O(\max(n, m))$, where n and m are the lengths of the two binary strings.

Space Complexity: $O(\max(n, m))$ for storing the resulting binary string.

Solution

The strategy is to iterate over the input strings from the end to the beginning. At each step, calculate the sum of corresponding bits and the existing carry. Use the modulo operation ($\% 2$) to determine the current digit and integer division ($// 2$) to update the carry. Once all digits have been processed, reverse the result to obtain the final binary string.

#136 Single Number [Easy]

Key Insights

- Using bitwise XOR: XOR-ing a number with itself cancels out to 0.
- XOR is both commutative and associative, so the order of operations does not matter.
- A single traversal (linear time) and constant extra space is sufficient for solving the problem.

Space & Time

Time Complexity: $O(n)$ – We only traverse the array once.

Space Complexity: $O(1)$ – Only a single extra variable is used regardless of input size.

Solution

We can solve this problem by initializing a variable to 0 and then traversing the array while XOR-ing each element with the variable. Due to the properties of XOR, pairs of identical numbers will cancel each other out ($x \text{ XOR } x = 0$) and the unique number will be left as the final result. This approach uses constant extra space and performs in linear time.

#190 Reverse Bits [Easy]

Key Insights

- The input is a binary string of fixed length (32 bits).
- Reversing the bits is equivalent to reversing the string.
- The reversed binary string can be converted back into its integer representation.
- Since the number of bits is constant (32), the solution can be achieved in constant time and constant space.
- For performance optimization when this function is called many times, caching may be applied for common intermediate results.

Space & Time

Time Complexity: $O(1)$ – We always process 32 bits regardless of the input.

Space Complexity: $O(1)$ – Only constant extra space is used.

Solution

We solve the problem by reversing the 32-character binary string representing the unsigned integer. Once reversed, the new binary string is converted into its integer value. An alternative solution involves using bitwise operations

where you iterate over each bit, shift the result to the left, and add the current bit. This approach does the reversal one bit at a time. The chosen approach leverages string reversal which is straightforward to implement and understand.

#191 Number of 1 Bits [Easy]

Key Insights

- The problem is essentially counting the number of 1s in the binary representation of a number.
- A common efficient approach uses bit manipulation: repeatedly clear the lowest set bit until n becomes zero.
- The expression $n \& (n - 1)$ clears the lowest set bit of n .
- This method only iterates as many times as there are set bits, making it efficient.

Space & Time

Time Complexity: $O(k)$, where k is the number of set bits, worst-case $O(\log n)$ (or $O(1)$ considering 32-bit integers).

Space Complexity: $O(1)$.

Solution

To solve the problem, we use the bit manipulation trick $n \& (n - 1)$ which removes the lowest set bit from n . The algorithm is as follows:

- Initialize a counter to 0.
- While n is not zero, update n by $n = n \& (n - 1)$, and increment the counter.
- The counter will hold the number of set bits by the end of the loop. This approach leverages efficient bit-level operations and works well even when the function is called frequently.

#268 Missing Number [Easy]

Key Insights

- The range of numbers is continuous from 0 to n , but one number is missing.
- The sum of numbers from 0 to n can be computed using the arithmetic sum formula.
- Subtracting the sum of the given array from the expected sum gives the missing number.
- There is a follow-up challenge to solve the problem in $O(n)$ time and $O(1)$ extra space.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

We compute the expected sum of all numbers from 0 to n using the formula $\text{sum} = n*(n+1)/2$. Then, we compute the actual sum of the numbers in the array. The missing number is obtained by subtracting the actual sum from the expected sum. This approach uses arithmetic operations ($O(1)$ extra space) and loops over the array once ($O(n)$ time).

#338 Counting Bits [Easy]

Key Insights

- We can use dynamic programming to build the solution by utilizing the count of bits for smaller numbers.
- The relationship $\text{dp}[i] = \text{dp}[i \gg 1] + (i \& 1)$ holds, where $i \gg 1$ gives the count for i divided by 2 (dropping the least significant bit) and $(i \& 1)$ checks if the least significant bit is 1.
- This approach computes the result for each number in constant time, resulting in a linear time solution.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(n)$

Solution

We use a dynamic programming approach where an array (or list) dp is initialized with size $n+1$. The key idea is to iterate from 1 to n and for each number, use the formula $\text{dp}[i] = \text{dp}[i \gg 1] + (i \& 1)$.

- The expression $(i >> 1)$ effectively divides i by 2, giving the count of 1's for that half number.
- The $(i \& 1)$ operation checks if i is odd, adding 1 if true. This method ensures each $dp[i]$ is computed in constant time, leading to an overall $O(n)$ time complexity.

#78 Subsets [Medium]

Key Insights

- The problem is equivalent to generating the power set of the given set.
- A recursive backtracking approach can be used to explore both including and excluding each element.
- Iterative (bit manipulation) solutions are also possible since there are 2^n subsets in total.
- The maximum array length is small (up to 10), making exponential time solutions feasible.

Space & Time

Time Complexity: $O(2^n * n)$ – There are 2^n subsets and creating each subset may take up to $O(n)$ time.

Space Complexity: $O(2^n * n)$ – Space for storing all subsets. The recursion stack has a maximum depth of $O(n)$.

Solution

We solve the problem using backtracking, where we decide for each element whether to include it in the current subset or not. We recursively build all subsets starting at an empty list and at each step appending the current subset to our result list. We can also use iterative bit manipulation but here we focus on the backtracking approach. This algorithm leverages recursion and a list to maintain the current state, leading to a clear and concise implementation.

#90 Subsets II [Medium]

Key Insights

- Sort the array first so that duplicate elements are adjacent.
- Use backtracking to generate all possible subsets.
- Skip duplicate elements in the recursion to avoid forming duplicate subsets.
- The use of sorted order and conditionally skipping elements is the trick to handle duplicates.

Space & Time

Time Complexity: $O(2^n * n)$ since each subset creation may take $O(n)$ in the worst case.

Space Complexity: $O(2^n * n)$ for storing the subsets, plus $O(n)$ for recursion stack.

Solution

The solution uses a backtracking technique that builds subsets incrementally. The input array is first sorted to bring duplicates together. During recursion, if the current element is the same as the previous one and it has not been used in the current recursion path, it is skipped to prevent duplicate subsets. This ensures that each subset is unique. The algorithm stores each valid subset by copying the current subset state into the result list.

#287 Find the Duplicate Number [Medium]

Key Insights

- Since there are $n+1$ elements with values only from 1 to n , by the pigeonhole principle at least one number must be repeated.
- The problem can be approached by mapping the array values to indices, forming a cycle structure.
- Floyd's Tortoise and Hare algorithm (cycle detection) can be applied to find the duplicate number in linear time and constant space.
- There is no need for extra data structures like hash sets or alterations to the original array, satisfying the space and array-modification constraints.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

The solution leverages Floyd's Tortoise and Hare cycle detection algorithm. Think of each array element as a pointer to another index, forming a linked list with a cycle (the duplicate number creates the cycle). The algorithm works in two phases:

– Detect a meeting point within the cycle by having two pointers (tortoise and hare) move at different speeds. – Find the cycle entrance by resetting one pointer to the start and moving both pointers at the same speed. The meeting point reveals the duplicate number.

This approach provides an elegant solution that satisfies both linear runtime and constant space requirements.

#1506 Find Root of N-Ary Tree [Medium]

Key Insights

- Every node except the root appears as a child of another node.
- By summing all node values and then subtracting the sum of all children node values, the remaining value corresponds to the root.
- This subtraction trick allows us to identify the root in a single pass of the data structure without extra memory for tracking child nodes.

Space & Time

Time Complexity: $O(n)$ where n is the number of nodes, since we iterate through all nodes and their children.

Space Complexity: $O(1)$ extra space using arithmetic accumulators.

Solution

The solution calculates two sums: one for all nodes' values and one for all children nodes' values. The difference between these gives the value of the root node since every node's value (except the root's) is added once as a child. Finally, we iterate over the nodes to find the node with the computed root value and return it. This approach meets the requirement of constant space complexity and linear time.

Letter Combinations of a Phone Number

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Backtracking](#)

Lists: Grind 169

Problem:

Given a string containing digits from 2-9 inclusive, return all possible letter combinations that the number could represent. Return the answer in any order.

A mapping of digits to letters (just like on the telephone buttons) is given below. Note that 1 does not map to any letters.

Example 1:

Input: digits = "23"

Output: ["ad", "ae", "af", "bd", "be", "bf", "cd", "ce", "cf"]

Example 2:

Input: digits = "2"

Output: ["a", "b", "c"]

Constraints:

- $1 \leq \text{digits.length} \leq 4$

- `digits[i]` is a digit in the range ['2', '9'].

Generate Parentheses

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[String](#) · [Dynamic Programming](#) · [Backtracking](#)

Lists: Grind 169

Problem:

Given n pairs of parentheses, write a function to generate all combinations of well-formed parentheses.

Example 1:

Input: n = 3

Output: ["((()))", "(()())", "(())()", "()(())", "()()()"]

Example 2:

Input: n = 1

Output: ["()"]

Constraints:

- $1 \leq n \leq 8$

[*] Backtracking — Pattern Solution (matched from community answers)

Python

```
def generateParenthesis(n):
    # List to store valid combinations
    result = []

    # Helper function for backtracking
    def backtrack(current, open_count, close_count):
        # If current string reaches the maximum length, it's a valid combination
        if len(current) == 2 * n:
            result.append(current)
            return
        # If we can add an opening parenthesis, do it
        if open_count < n:
            backtrack(current + '(', open_count + 1, close_count)
        # If adding a closing parenthesis maintains the validity, do it
        if close_count < open_count:
            backtrack(current + ')', open_count, close_count + 1)

    # Start the recursion with an empty string and zero counts for both
    backtrack("", 0, 0)
    return result

# Example usage:
print(generateParenthesis(3))
```

Combination Sum

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Problem:

Given an array of distinct integers `candidates` and a target integer `target`, return a list of all unique combinations of candidates where the chosen numbers sum to `target`. You may return the combinations in any order.

The same number may be chosen from `candidates` an unlimited number of times. Two combinations are unique if the frequency of at least one of the chosen numbers is different.

The test cases are generated such that the number of unique combinations that sum up to `target` is less than 150 combinations for the given input.

Example 1:

Input: `candidates = [2,3,6,7]`, `target = 7`

Output: `[[2,2,3],[7]]`

Explanation:

2 and 3 are candidates, and $2 + 2 + 3 = 7$. Note that 2 can be used multiple times.

7 is a candidate, and $7 = 7$.

These are the only two combinations.

Example 2:

Input: `candidates = [2,3,5]`, `target = 8`

Output: `[[2,2,2,2],[2,3,3],[3,5]]`

Example 3:

Input: `candidates = [2]`, `target = 1`

Output: `[]`

Constraints:

- $1 \leq \text{candidates.length} \leq 30$
- $2 \leq \text{candidates}[i] \leq 40$
- All elements of `candidates` are distinct.
- $1 \leq \text{target} \leq 40$

>> Brute Force [Backtracking] Interview Prep**Python**

```
# Brute Force Approach
class Solution:
    def combinationSum(self, candidates, target):
        # Brute Force  $O(n^{\text{target/min}})$  – recursion without pruning
        result = []
        def backtrack(start, path, remain):
            if remain == 0:
                result.append(list(path)); return
            if remain < 0: return
            for i in range(start, len(candidates)):
                path.append(candidates[i])
                backtrack(i, path, remain - candidates[i])
                path.pop()
            backtrack(0, [], target)
        return result
```

Python

Python

```
# Function to find all unique combinations that sum to the target
def combinationSum(candidates, target):
    # List to store all valid combinations
    result = []
    # Sort candidates to facilitate pruning of the search
    candidates.sort()

    # Recursive helper function for backtracking
    def backtrack(remaining, start, path):
        # If remaining is 0, path is a valid combination so add a copy of it to result
        if remaining == 0:
            result.append(list(path))
            return
        # Loop through candidates starting from the current index
        for i in range(start, len(candidates)):
            # If candidate is greater than remaining, break out for efficiency
            if candidates[i] > remaining:
                break
            # Include candidate in the current combination path
            path.append(candidates[i])
            # Recursively call backtrack with updated remaining and same index (allowing reuse)
            backtrack(remaining - candidates[i], i, path)
            # Backtrack by removing the candidate added in this iteration
            path.pop()

    # Start backtracking from index 0 with an empty path
    backtrack(target, 0, [])
    return result

# Example usage
print(combinationSum([2,3,6,7], 7))

Permutations

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Backtracking](#)

Lists: Grind 169

Problem:

Given an array `nums` of distinct integers, return all the possible permutations. You can return the answer in any order.

Example 1:

Input: `nums = [1,2,3]`
 Output: `[[1,2,3],[1,3,2],[2,1,3],[2,3,1],[3,1,2],[3,2,1]]`

Example 2:

Input: `nums = [0,1]`
 Output: `[[0,1],[1,0]]`

Example 3:

Input: `nums = [1]`
 Output: `[[1]]`

Constraints:

- $1 \leq \text{nums.length} \leq 6$
- $-10 \leq \text{nums}[i] \leq 10$
- All the integers of nums are unique.

Python

```
# Brute Force Approach
class Solution:
    def permute(self, nums):
        # Brute Force  $O(n! \cdot n)$  – itertools.permutations (or full recursion)
        from itertools import permutations as perms
        return [list(p) for p in perms(nums)]
```

Python

Python

```
def permute(nums):
    result = []

    def backtrack(current, remaining):
        # If no remaining elements, current permutation is complete.
        if not remaining:
            result.append(current.copy())
            return
        # Explore each candidate number.
        for i in range(len(remaining)):
            # Add the chosen number to the current permutation.
            current.append(remaining[i])
            # Recursively generate permutations with the remaining numbers.
            backtrack(current, remaining[:i] + remaining[i+1:])
            # Backtrack by removing the chosen number.
            current.pop()

    backtrack([], nums)
    return result

# Example usage:
print(permute([1,2,3]))
```

Python

```

#####

...

In Python 3, both the `discard()` and `remove()` methods of a set object are used to remove an element from the set, but there is one key difference:

- * `discard()` removes the specified element from the set if it is present, but does nothing if the element is not present.
- * `remove()` removes the specified element from the set if it is present, but raises a `KeyError` exception if the element is not present.

```

>>> a
{33, 66, 11, 44, 22, 55}
>>> a.discard(22)
>>> a
{33, 66, 11, 44, 55}

```

```

>>> a.discard(200)
>>>
>>> a.remove(200)

Word Search

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [String](#) · [Backtracking](#) · [Matrix](#)

Lists: Grind 169

Problem:

Given an $m \times n$ grid of characters board and a string word, return true if word exists in the grid.

The word can be constructed from letters of sequentially adjacent cells, where adjacent cells are horizontally or vertically neighboring. The same letter cell may not be used more than once.

Example 1:

A	B	C	E
S	F	C	S
A	D	E	E

Input: board = [["A","B","C","E"],["S","F","C","S"],["A","D","E","E"]], word = "ABCCED"
Output: true

Example 2:

A	B	C	E
S	F	C	S
A	D	E	E

Input: board = [["A","B","C","E"],["S","F","C","S"],["A","D","E","E"]], word = "SEE"
Output: true

Example 3:

A	B	C	E
S	F	C	S
A	D	E	E

Input: board = [["A","B","C","E"],["S","F","C","S"],["A","D","E","E"]], word = "ABCB"
Output: false

Constraints:

- $m == \text{board.length}$
- $n = \text{board}[i].\text{length}$
- $1 \leq m, n \leq 6$
- $1 \leq \text{word.length} \leq 15$
- board and word consists of only lowercase and uppercase English letters.

Follow up: Could you use search pruning to make your solution faster with a larger board?

MEDIUM

Path Sum II

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Backtracking](#) · [Tree](#) · [DFS](#)

Lists: Grind 169

Problem:

Given the root of a binary tree and an integer `targetSum`, return all root-to-leaf paths where the sum of the node values in the path equals `targetSum`. Each path should be returned as a list of the node values, not node references.

A root-to-leaf path is a path starting from the root and ending at any leaf node. A leaf is a node with no children.

Example 1:

Input: root = [5,4,8,11,null,13,4,7,2,null,null,5,1], targetSum = 22

Output: [[5,4,11,2],[5,8,4,5]]

Explanation: There are two paths whose sum equals targetSum:

$5 + 4 + 11 + 2 = 22$

$5 + 8 + 4 + 5 = 22$

Example 2:

Input: root = [1,2,3], targetSum = 5

Output: []

Example 3:

Input: root = [1,2], targetSum = 0

Output: []

Constraints:

- The number of nodes in the tree is in the range [0, 5000].
- $-1000 \leq \text{Node.val} \leq 1000$
- $-1000 \leq \text{targetSum} \leq 1000$

Sudoku Solver

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Backtracking](#) · [Matrix](#)

Lists: Grind 169

Problem:

Write a program to solve a Sudoku puzzle by filling the empty cells.

A sudoku solution must satisfy all of the following rules:

1. Each of the digits 1–9 must occur exactly once in each row.
2. Each of the digits 1–9 must occur exactly once in each column.
3. Each of the digits 1–9 must occur exactly once in each of the 9 3x3 sub-boxes of the grid.

The '.' character indicates empty cells.

Example 1:

5	3			7				
6			1	9	5			
	9	8					6	
8				6				3
4			8		3			1
7				2				6
	6					2	8	
			4	1	9			5
				8			7	9

Input: board = `[["5","3",".",".","7",".",".",".","."],["6",".",".","1","9","5",".",".","."],[".","9","8",".",".",".","6",".","."],["8",".",".",".","6",".",".","3"],["4",".",".","8",".","3",".",".","1"],["7",".",".","2",".",".","6"],[".","6",".",".","2","8","."],[".",".","4","1","9",".","5"],[".",".","8",".","7","9"]]`

Output: `[["5","3","4","6","7","8","9","1","2"],["6","7","2","1","9","5","3","4","8"],["1","9","8","3","4","2","5","6","7"],["8","5","9","7","6","1","4","2","3"],["4","2","6","8","5","3","7","9","1"],["7","1","3","9","2","4","8","5","6"],["9","6","1","5","3","7","2","8","4"],["2","`

```
, "8", "7", "4", "1", "9", "6", "3", "5"], ["3", "4", "5", "2", "8", "6", "1", "7", "9"]]
```

Explanation: The input board is shown above and the only valid solution is shown below:

Constraints:

- `board.length == 9`
- `board[i].length == 9`
- `board[i][j]` is a digit or '.'.
- It is guaranteed that the input board has only one solution.

HARD

N-Queens

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Backtracking](#)

Lists: Grind 169

Problem:

The n-queens puzzle is the problem of placing n queens on an n x n chessboard such that no two queens attack each other.

Given an integer n, return all distinct solutions to the n-queens puzzle. You may return the answer in any order.

Each solution contains a distinct board configuration of the n-queens' placement, where 'Q' and '.' both indicate a queen and an empty space, respectively.

Example 1:

Input: n = 4

Output: [".Q..","...Q","Q...","..Q."],["..Q.", "Q...", "...Q", ".Q.."]]

Explanation: There exist two distinct solutions to the 4-queens puzzle as shown above

Example 2:

Input: n = 1

Output: [["Q"]]

Constraints:

- $1 \leq n \leq 9$

HARD

Word Ladder II

Problem:

A transformation sequence from word `beginWord` to word `endWord` using a dictionary `wordList` is a sequence of words `beginWord -> s1 -> s2 -> ... -> sk` such that:

- Every adjacent pair of words differs by a single letter.
- Every s_i for $1 \leq i \leq k$ is in `wordList`. Note that `beginWord` does not need to be in `wordList`.
- $s_k == \text{endWord}$

Given two words, `beginWord` and `endWord`, and a dictionary `wordList`, return all the shortest transformation sequences from `beginWord` to `endWord`, or an empty list if no such sequence exists. Each sequence should be returned as a list of the words `[beginWord, s1, s2, ..., sk]`.

Example 1:

Input: `beginWord = "hit", endWord = "cog", wordList = ["hot","dot","dog","lot","log","cog"]`

Output: `[["hit","hot","dot","dog","cog"],["hit","hot","lot","log","cog"]]`

Explanation: There are 2 shortest transformation sequences:

`"hit" -> "hot" -> "dot" -> "dog" -> "cog"`

`"hit" -> "hot" -> "lot" -> "log" -> "cog"`

Example 2:

Input: `beginWord = "hit", endWord = "cog", wordList = ["hot","dot","dog","lot","log"]`

Output: `[]`

Explanation: The `endWord "cog"` is not in `wordList`, therefore there is no valid transformation sequence.

Constraints:

- $1 \leq \text{beginWord.length} \leq 5$
- $\text{endWord.length} == \text{beginWord.length}$
- $1 \leq \text{wordList.length} \leq 500$
- $\text{wordList}[i].\text{length} == \text{beginWord.length}$
- `beginWord`, `endWord`, and `wordList[i]` consist of lowercase English letters.
- `beginWord != endWord`
- All the words in `wordList` are unique.
- The sum of all shortest transformation sequences does not exceed 105.

HARD

Number of Squareful Arrays

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Math](#) · [Dynamic Programming](#) · [Backtracking](#)

Lists: Denny Zhang

Problem:

An array is squareful if the sum of every pair of adjacent elements is a perfect square.

Given an integer array `nums`, return the number of permutations of `nums` that are squareful.

Two permutations `perm1` and `perm2` are different if there is some index `i` such that `perm1[i] != perm2[i]`.

Example 1:

Input: `nums = [1,17,8]`

Output: 2

Explanation: `[1,8,17]` and `[17,8,1]` are the valid permutations.

Example 2:

Input: `nums = [2,2,2]`

Output: 1

Constraints:

- $1 \leq \text{nums.length} \leq 12$
- $0 \leq \text{nums}[i] \leq 109$

Quick Review — Backtracking 10 questions · insights · complexity · solution

#17 Letter Combinations of a Phone Number [Medium]

Key Insights

- Use a mapping from digits to the respective letters as defined by a telephone keypad.
- Backtracking is an ideal approach to generate all possible combinations.
- Each digit adds a level in the recursive tree where you append one letter at a time.
- Handling edge cases such as an empty input string is crucial.

Space & Time

Time Complexity: $O(4^n * n)$ where n is the length of the input string (each digit may map to up to 4 letters and adding a combination takes $O(n)$ time).

Space Complexity: $O(n)$ for the recursion call stack, not counting the space required for storing the output.

Solution

We can solve the problem using a backtracking algorithm. First, we define a dictionary mapping each digit to its corresponding letters. Then we initiate a recursive function called `backtrack` that takes the current combination and the index of the next digit to process. At each call, if the combination is complete (length equal to the input string), we add it to the result list. Otherwise, we iterate through the letters corresponding to the current digit, append a letter to the combination, and recursively call `backtrack` with the next index. This approach ensures that all possible letter combinations are generated.

#22 Generate Parentheses [Medium]

Key Insights

- Use a backtracking approach to build the valid combinations step by step.
- At any recursion step, you can add an opening parenthesis if you still have one available.
- You can add a closing parenthesis only if it would not result in an invalid sequence (i.e., the number of closing parentheses is less than the number of opening ones).
- The solution leverages recursion to explore all potential valid sequences while pruning invalid paths early.

Space & Time

Time Complexity: $O(4^n / (n^{(3/2)}))$

Space Complexity: $O(n)$ for the recursion stack, plus space for storing all valid combinations.

Solution

The solution uses a recursive backtracking technique to generate the combinations. The algorithm maintains counters for the number of '(' and ')' added to the current string. It recursively adds a '(' if the count is less than n and adds a ')' if doing so does not make the string invalid (i.e., if the count of ')' is less than the count of '('). When a valid combination reaches a length of $2*n$, it is added to the result list.

#39 Combination Sum [Medium]

Key Insights

- Backtracking is a natural fit to explore all potential combinations.
- Sorting candidates simplifies the process by allowing early termination if the current candidate exceeds the remaining target.
- Recursion is used to build combinations and backtrack once the current path exceeds or meets the target.
- The same candidate can be reused in the combination, so the recursive call does not advance the index.

Space & Time

Time Complexity: $O(2^{(\text{target}/\min(\text{candidates}))})$ in the worst case where many combinations are possible.

Space Complexity: $O(\text{target}/\min(\text{candidates}))$ for the recursion stack and temporary space used to store combinations.

Solution

The solution uses a backtracking approach. First, sort the candidates to enable pruning of recursive calls once the candidate exceeds the remaining target. A recursive helper function builds up a combination, subtracting the candidate value from the target until it reaches zero (a valid combination) or becomes negative (an invalid path). The recursion allows the same candidate to be chosen again. Each valid combination is then added to the result list.

#46 Permutations [Medium]

Key Insights

- Use backtracking to generate all possible permutations.
- Build each permutation by selecting numbers one at a time.
- When the current permutation reaches the length of nums, add it to the result.
- Backtracking allows you to undo choices and explore different orderings.

Space & Time

Time Complexity: $O(n * n!)$ – There are $n!$ permutations, and constructing each permutation takes $O(n)$ time.

Space Complexity: $O(n)$ – Recursion depth is limited to n , plus additional space for the current permutation.

Solution

The solution employs a backtracking algorithm. A helper function is used to build permutations recursively. At each step, the algorithm iterates through the available numbers, adds one to the current permutation if it has not been used yet, and recurses to handle the remaining numbers. Once the current permutation matches the length of the input array, it is added to the result list. Then, by "backtracking" (removing the last number added), the algorithm explores alternative possibilities. This systematic exploration ensures that all possible permutations are generated.

#79 Word Search [Medium]

Key Insights

- Use Depth-First Search (DFS) to explore each cell in the board as a potential starting point.
- Employ backtracking to mark cells as visited when exploring a path and revert them back when backtracking.
- Check boundary conditions and ensure the current cell's character matches the corresponding character in the word.
- Given the small grid and word sizes, a recursive solution is both feasible and straightforward.
- Search pruning can be applied by stopping a DFS branch as soon as the current path does not match the prefix of the target word.

Space & Time

Time Complexity: $O(m * n * 3^L)$, where L is the length of the word (each DFS may branch to at most 3 further cells, excluding the coming cell).

Space Complexity: $O(L)$ due to recursion call stack (where L is the word length).

Solution

The solution uses DFS with backtracking to traverse the grid. For each cell, we:

- Check if the cell matches the first character of the word.
- Recursively explore the adjacent cells (up, down, left, right) while marking the current cell as visited.
- If the path does not lead to a complete match, backtrack by resetting the visited cell.
- The DFS stops if all characters in the word have been found in sequence.

The algorithm leverages in-place modifications (or an auxiliary visited array) to avoid revisiting cells while exploring a candidate path.

#113 Path Sum II [Medium]

Key Insights

- Use Depth-First Search (DFS) to explore all paths from the root to the leaves.

- Backtracking is essential: add the current node value to the path before the recursive calls and remove it (backtrack) after exploring both subtrees.
- At each leaf, check if the accumulated sum equals targetSum.
- Maintain a running sum or subtract the current node's value from the target sum as you traverse.

Space & Time

Time Complexity: $O(N^2)$ in the worst-case scenario (where N is the number of nodes) when most nodes are leaf nodes, since each potential path copy operation can be $O(N)$.

Space Complexity: $O(N)$ for the recursion stack and the path storage, where N is the height of the tree.

Solution

We solve the problem using a recursive DFS approach combined with backtracking. The idea is to traverse the tree while maintaining the current path and the remaining sum needed to reach targetSum. When a leaf node is reached (node with no children), we check if the remaining sum equals the leaf's value – if yes, we record a copy of the current path.

Data structures and algorithmic approaches used:

– Recursion for DFS: to traverse to each leaf. – List (or Array) for storing the current path. – Backtracking: to remove the last added element when stepping back up the recursion stack. – Copying the path when a valid leaf is reached to store it in the final result.

A common pitfall is to forget to backtrack, which would result in incorrect paths being recorded.

#37 Sudoku Solver [Hard]

Key Insights

- Use backtracking to explore digit placements for each empty cell.
- Validate placements by ensuring that the chosen digit is not already present in the corresponding row, column, or 3x3 sub-box.
- Employ recursion to fill the board incrementally and backtrack upon encountering invalid configurations.
- Although the worst-case time complexity is exponential, the fixed board size (9x9) keeps the problem computationally manageable.

Space & Time

Time Complexity: In the worst-case scenario, the algorithm can explore up to $O(9^n)$ possibilities where n is the number of empty cells. However, since n is at most 81 and many branches are pruned early, the practical runtime is far less.

Space Complexity: $O(n)$ due to the recursion stack, where n is the number of empty cells; given the board's fixed size, this space is constant in practice.

Solution

The solution uses a backtracking approach. For each empty cell on the board, we attempt to place a digit from '1' to '9'. Before placing a digit, we check if the placement is valid by ensuring that:

– The digit is not already present in the same row. – The digit is not already present in the same column. – The digit is not already present in the corresponding 3x3 sub-box.

If a valid digit is found, we place it on the board and recursively attempt to solve the rest of the board. If no valid digit can be placed, the algorithm backtracks by reverting the last move and trying a different digit. This recursive search continues until the board is completely filled with a valid Sudoku configuration.

#51 N-Queens [Hard]

Key Insights

- Use backtracking to explore potential positions row by row.
- Use sets to track which columns and diagonals are under attack.
- Diagonals can be tracked by $(row - col)$ and $(row + col)$, ensuring that queens do not conflict along any diagonal.
- Recursively build each valid board configuration and backtrack when a conflict arises.

Space & Time

Time Complexity: $O(n!)$ in the worst-case scenario, as the solution explores permutations for queen placements.

Space Complexity: $O(n^2)$ for storing board configurations and $O(n)$ for recursion stack and conflict-tracking sets.

Solution

We use a backtracking algorithm that places queens row by row. For each row, we try placing a queen in each column. Before placing, we check if the column, main diagonal ($\text{row} - \text{col}$), and anti-diagonal ($\text{row} + \text{col}$) are free using dedicated sets. If a queen can be safely placed, we mark the column and diagonals as occupied and recurse to the next row. Once all rows are processed, the board configuration is a valid solution and is added to the result. After that, we backtrack by unmarking the sets and removing the queen from the board. This systematic approach ensures all possible configurations are considered.

#126 Word Ladder II [Hard]

Key Insights

- Use Breadth-First Search (BFS) to traverse level-by-level and capture only the shortest paths.
- Build a parent mapping during BFS to record which words lead to each newly discovered word.
- Once the shortest path is found via BFS, use backtracking (or DFS) from endWord to reconstruct all transformation sequences.
- Remove words as they are visited within a level to avoid unnecessary revisits and cycles.
- The solution must handle multiple shortest paths, so maintaining a list of predecessors for each word is crucial.

Space & Time

Time Complexity: $O(N * L * 26)$ where N is the number of words in the wordList and L is the length of each word. This accounts for checking all possible one-letter transformations.

Space Complexity: $O(N * L)$ for storing the parent mapping and maintaining the BFS queue and other auxiliary data structures.

Solution

We solve the problem in two major phases:

– Use BFS to explore from beginWord to endWord. During BFS, record all parents for each word encountered. This ensures we capture all possible predecessors that yield a shortest transformation. – Once the BFS completes (once endWord is reached), use backtracking (DFS) beginning from the endWord and moving backwards via the parent mapping to reconstruct all transformation sequences in reverse. Finally, reverse each sequence to present it from beginWord to endWord.

This two-phase approach guarantees that only the shortest paths are reconstructed, as BFS ensures level-by-level exploration.

#996 Number of Squareful Arrays [Hard]

Key Insights

- The problem requires ensuring adjacent pairs sum up to a perfect square.
- Sorting the array helps in efficiently handling duplicates; when iterating in the backtracking, skip duplicate elements to avoid overcounting.
- For each valid candidate, check that the sum with the previous number (if any) is a perfect square.
- Use backtracking (DFS) to generate all valid permutations while maintaining a visited flag for each index.
- Since the array may contain duplicates, extra care is taken to only use each occurrence in a controlled order (i.e., if two identical numbers exist, only the first unvisited instance can be chosen at a given recursive call).

Space & Time

Time Complexity: $O(n^2 * 2^n)$ in the worst-case scenario due to exploring all bitmask states with n elements and checking pairwise sums.

Space Complexity: $O(n)$ for recursion and $O(n)$ for the visited flag, plus potentially $O(2^n * n)$ for memoization if implemented.

Solution

The solution uses a backtracking algorithm to explore all permutations. The array is first sorted to handle duplicates. A helper function checks if a number is a perfect square and is used to validate that the sum of every adjacent pair is a perfect square. During DFS, a visited array is maintained to track elements included so far. Skipping duplicate elements (unless the earlier duplicate was used) is essential to avoid overcounting. This approach ensures that every valid permutation is considered exactly once.

#286

MEDIUM

Walls and Gates

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [BFS](#) · [Matrix](#)

Lists: Premium 98

Problem:

You are given an $m \times n$ grid rooms initialized with these three possible values.

- -1 A wall or an obstacle.
- 0 A gate.
- INF Infinity means an empty room. We use the value $231 - 1 = 2147483647$ to represent INF as you may assume that the distance to a gate is less than 2147483647.

Fill each empty room with the distance to its nearest gate. If it is impossible to reach a gate, it should be filled with INF.

Example 1:

Input: rooms = [[2147483647,-1,0,2147483647],[2147483647,2147483647,2147483647,-1],[2147483647,-1,2147483647,-1],[0,-1,2147483647,2147483647]]

Output: [[3,-1,0,1],[2,2,1,-1],[1,-1,2,-1],[0,-1,3,4]]

Example 2:

Input: rooms = [[-1]]

Output: [[-1]]

Constraints:

- $m == \text{rooms.length}$
- $n == \text{rooms}[i].\text{length}$

- $1 \leq m, n \leq 250$
- `rooms[i][j]` is `-1`, `0`, or `231 - 1`.

Coin Change

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Dynamic Programming](#) · [BFS](#)

Lists: Grind 169

Problem:

You are given an integer array `coins` representing coins of different denominations and an integer `amount` representing a total amount of money.

Return the fewest number of coins that you need to make up that amount. If that amount of money cannot be made up by any combination of the coins, return `-1`.

You may assume that you have an infinite number of each kind of coin.

Example 1:

Input: `coins = [1,2,5]`, `amount = 11`

Output: `3`

Explanation: `11 = 5 + 5 + 1`

Example 2:

Input: `coins = [2]`, `amount = 3`

Output: `-1`

Example 3:

Input: `coins = [1]`, `amount = 0`

Output: `0`

Constraints:

- `1 <= coins.length <= 12`
- `1 <= coins[i] <= 231 - 1`
- `0 <= amount <= 104`

01 Matrix

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [BFS](#) · [Matrix](#)

Lists: Grind 169 | Denny Zhang

Problem:

Given an $m \times n$ binary matrix `mat`, return the distance of the nearest 0 for each cell.

The distance between two cells sharing a common edge is 1.

Example 1:

0	0	0
0	1	0
0	0	0

Input: mat = [[0,0,0],[0,1,0],[0,0,0]]

Output: [[0,0,0],[0,1,0],[0,0,0]]

Example 2:

0	0	0
0	1	0
1	1	1

Input: mat = [[0,0,0],[0,1,0],[1,1,1]]

Output: [[0,0,0],[0,1,0],[1,2,1]]

Constraints:

- $m == \text{mat.length}$
- $n == \text{mat}[i].\text{length}$
- $1 \leq m, n \leq 104$

- $1 \leq m * n \leq 104$
- `mat[i][j]` is either 0 or 1.
- There is at least one 0 in `mat`.

MEDIUM

Rotting Oranges

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [BFS](#) · [Matrix](#)

Lists: Grind 169

Problem:

You are given an $m \times n$ grid where each cell can have one of three values:

- 0 representing an empty cell,
- 1 representing a fresh orange, or
- 2 representing a rotten orange.

Every minute, any fresh orange that is 4-directionally adjacent to a rotten orange becomes rotten.

Return the minimum number of minutes that must elapse until no cell has a fresh orange. If this is impossible, return -1.

Example 1:

Input: grid = [[2,1,1],[1,1,0],[0,1,1]]

Output: 4

Example 2:

Input: grid = [[2,1,1],[0,1,1],[1,0,1]]

Output: -1

Explanation: The orange in the bottom left corner (row 2, column 0) is never rotten, because rotting only happens 4-directionally.

Example 3:

Input: grid = [[0,2]]

Output: 0

Explanation: Since there are already no fresh oranges at minute 0, the answer is just 0.

Constraints:

- $m == \text{grid.length}$
- $n == \text{grid}[i].\text{length}$
- $1 \leq m, n \leq 10$
- $\text{grid}[i][j]$ is 0, 1, or 2.

Minimum Knight Moves

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

BFS

Lists: Grind 169 | Premium 98

Problem:

In an infinite chess board with coordinates from $-\infty$ to $+\infty$, you have a knight at square $[0, 0]$.

A knight has 8 possible moves it can make, as illustrated below. Each move is two squares in a cardinal direction, then one square in an orthogonal direction.

Return the minimum number of steps needed to move the knight to the square $[x, y]$. It is guaranteed the answer exists.

Example 1:

Input: $x = 2, y = 1$

Output: 1

Explanation: $[0, 0] \rightarrow [2, 1]$

Example 2:

Input: $x = 5, y = 5$

Output: 4

Explanation: $[0, 0] \rightarrow [2, 1] \rightarrow [4, 2] \rightarrow [3, 4] \rightarrow [5, 5]$

Constraints:

- $-300 \leq x, y \leq 300$
- $0 \leq |x| + |y| \leq 300$

MEDIUM

Shortest Path to Get Food

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [BFS](#) · [Matrix](#)

Lists: Grind 169

Problem:

You are starving and you want to eat food as quickly as possible. You want to find the shortest path to arrive at any food cell.

You are given an $m \times n$ character matrix, grid, of these different types of cells:

- '*' is your location. There is exactly one '*' cell.
- '#' is a food cell. There may be multiple food cells.
- 'O' is free space, and you can travel through these cells.

- 'X' is an obstacle, and you cannot travel through these cells.

You can travel to any adjacent cell north, east, south, or west of your current location if there is not an obstacle.

Return the length of the shortest path for you to reach any food cell. If there is no path for you to reach food, return -1.

Example 1:

Input: grid = [["X","X","X","X","X","X"], ["X","*","0","0","0","X"], ["X","0","0","#","0","X"], ["X","X","X","X","X","X"]]

Output: 3

Explanation: It takes 3 steps to reach the food.

Example 2:

Input: grid =
 [
 ["X", "X", "X", "X", "X"],
 ["X", "*", "X", "0", "X"],
 ["X", "0", "X", "#", "X"],
 ["X", "X", "X", "X", "X"]
]
 Output: -1
 Explanation: It is not possible to reach the food.

Example 3:

Input: grid = `[["X","X","X","X","X","X","X","X"],["X","*", "0","X","0","#","0","X"],["X","0","0","X","0","0","X","X"],["X","0","0","0","0","#","0","X"],["X","X","X","X","X","X","X","X"]]`

Output: 6

Explanation: There can be multiple food cells. It only takes 6 steps to reach the bottom food.

Example 4:

Input: grid = `[["X","X","X","X","X","X","X","X"],["X","*", "0","X","0","#","0","X"],["X","0","0","X","0","0","X","X"],["X","0","0","0","0","0","#","0","X"],["0","0","0","0","0","0","0","0"]]`

Output: 5

Constraints:

- `m == grid.length`
- `n == grid[i].length`
- `1 <= m, n <= 200`
- `grid[row][col]` is `'*'`, `'X'`, `'O'`, or `'#'`.
- The grid contains exactly one `'*'`.

HARD

Word Ladder

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Problem:

A transformation sequence from word `beginWord` to word `endWord` using a dictionary `wordList` is a sequence of words `beginWord` → `s1` → `s2` → ... → `sk` such that:

- Every adjacent pair of words differs by a single letter.
- Every `si` for $1 \leq i \leq k$ is in `wordList`. Note that `beginWord` does not need to be in `wordList`.
- `sk == endWord`

Given two words, `beginWord` and `endWord`, and a dictionary `wordList`, return the number of words in the shortest transformation sequence from `beginWord` to `endWord`, or 0 if no such sequence exists.

Example 1:

Input: `beginWord` = "hit", `endWord` = "cog", `wordList` = ["hot","dot","dog","lot","log","cog"]

Output: 5

Explanation: One shortest transformation sequence is "hit" → "hot" → "dot" → "dog" → "cog", which is 5 words long.

Example 2:

Input: `beginWord` = "hit", `endWord` = "cog", `wordList` = ["hot","dot","dog","lot","log"]

Output: 0

Explanation: The `endWord` "cog" is not in `wordList`, therefore there is no valid transformation sequence.

Constraints:

- $1 \leq \text{beginWord.length} \leq 10$
- `endWord.length == beginWord.length`
- $1 \leq \text{wordList.length} \leq 5000$
- `wordList[i].length == beginWord.length`
- `beginWord`, `endWord`, and `wordList[i]` consist of lowercase English letters.
- `beginWord != endWord`
- All the words in `wordList` are unique.

HARD

Shortest Distance from All Buildings

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [BFS](#) · [Matrix](#)

Lists: Premium 98

Problem:

You are given an $m \times n$ grid of values 0, 1, or 2, where:

- each 0 marks an empty land that you can pass by freely,
- each 1 marks a building that you cannot pass through, and
- each 2 marks an obstacle that you cannot pass through.

You want to build a house on an empty land that reaches all buildings in the shortest total travel distance. You can only move up, down, left, and right.

Return the shortest travel distance for such a house. If it is not possible to build such a house according to the above rules, return -1.

The total travel distance is the sum of the distances between the houses of the friends and the meeting point.

Example 1:

1	0	2	0	1
0	0	0	0	0
0	0	1	0	0

Input: grid = [[1,0,2,0,1],[0,0,0,0,0],[0,0,1,0,0]]

Output: 7

Explanation: Given three buildings at (0,0), (0,4), (2,2), and an obstacle at (0,2).

The point (1,2) is an ideal empty land to build a house, as the total travel distance of 3+3+1=7 is minimal.

So return 7.

Example 2:

Input: grid = [[1,0]]

Output: 1

Example 3:

Input: grid = [[1]]

Output: -1

Constraints:

- `m == grid.length`
- `n == grid[i].length`
- `1 <= m, n <= 50`
- `grid[i][j]` is either 0, 1, or 2.
- There will be at least one building in the grid.

Sliding Puzzle

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [BFS](#) · [Matrix](#)

Lists: Denny Zhang

Problem:

On an 2×3 board, there are five tiles labeled from 1 to 5, and an empty square represented by 0. A move consists of choosing 0 and a 4-directionally adjacent number and swapping it.

The state of the board is solved if and only if the board is $[[1,2,3],[4,5,0]]$.

Given the puzzle board board, return the least number of moves required so that the state of the board is solved. If it is impossible for the state of the board to be solved, return -1.

Example 1:

1	2	3
4	0	5

Input: board = $[[1,2,3],[4,0,5]]$

Output: 1

Explanation: Swap the 0 and the 5 in one move.

Example 2:

1	2	3
5	4	

Input: board = [[1,2,3],[5,4,0]]

Output: -1

Explanation: No number of moves will make the board solved.

Example 3:

4	1	2
5		3

Input: board = [[4,1,2],[5,0,3]]

Output: 5

Explanation: 5 is the smallest number of moves that solves the board.

An example path:

After move 0: [[4,1,2],[5,0,3]]

After move 1: [[4,1,2],[0,5,3]]

After move 2: [[0,1,2],[4,5,3]]

After move 3: [[1,0,2],[4,5,3]]

After move 4: [[1,2,0],[4,5,3]]

After move 5: [[1,2,3],[4,5,0]]

Constraints:

- board.length == 2
- board[i].length == 3
- 0 <= board[i][j] <= 5
- Each value board[i][j] is unique.

Bus Routes

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [BFS](#)

Lists: Grind 169

Problem:

You are given an array routes representing bus routes where routes[i] is a bus route that the ith bus repeats forever.

- For example, if routes[0] = [1, 5, 7], this means that the 0th bus travels in the sequence 1 -> 5 -> 7 -> 1 -> 5 -> 7 -> 1 -> ... forever.

You will start at the bus stop source (You are not on any bus initially), and you want to go to the bus stop target. You can travel between bus stops by buses only.

Return the least number of buses you must take to travel from source to target. Return -1 if it is not possible.

Example 1:

Input: routes = [[1,2,7],[3,6,7]], source = 1, target = 6

Output: 2

Explanation: The best strategy is take the first bus to the bus stop 7, then take the second bus to the bus stop 6.

Example 2:

Input: routes = [[7,12],[4,5,15],[6],[15,19],[9,12,13]], source = 15, target = 12

Output: -1

Constraints:

- $1 \leq \text{routes.length} \leq 500$.
- $1 \leq \text{routes}[i].\text{length} \leq 105$
- All the values of routes[i] are unique.
- $\text{sum}(\text{routes}[i].\text{length}) \leq 105$
- $0 \leq \text{routes}[i][j] < 106$
- $0 \leq \text{source}, \text{target} < 106$

    return -1

# Example usage:
# routes = [[1,2,7],[3,6,7]]
# print(numBusesToDestination(routes, 1, 6))

```

Quick Review — BFS 10 questions · insights · complexity · solution

#286 Walls and Gates [Medium]

Key Insights

- Use a multi-source Breadth-First Search (BFS) starting from all the gates, as this allows spreading the shortest distance to each empty room.
- Instead of starting from every empty room separately, starting from all gates simultaneously helps update all distances in one pass.
- Only update a room if the new calculated distance is smaller than its current value to prevent unnecessary processing.
- The problem is essentially a multi-source shortest path problem on a grid.

Space & Time

Time Complexity: $O(m * n)$ where m and n are the dimensions of the grid, as each cell is processed at most once.

Space Complexity: $O(m * n)$ in the worst-case scenario used by the BFS queue.

Solution

The solution uses a multi-source BFS algorithm by initially enqueueing all the gate positions (cells with value 0). Then, for each cell obtained from the queue, check its four possible neighbors (up, down, left, right). If a neighbor is an empty room (INF), update its distance to be the current cell's distance plus one, and then enqueue the neighbor to process further. This ensures that each empty room gets the minimum distance from any gate.

#322 Coin Change [Medium]

Key Insights

- Use a dynamic programming approach to build up a solution from smaller subproblems.
- Define $dp[x]$ as the minimum number of coins required for amount x .
- The recurrence relation is: $dp[x] = \min(dp[x], dp[x - \text{coin}] + 1)$ for each coin.
- Initialize $dp[0] = 0$ and set other values to a number larger than the maximum possible coins (amount+1 works as an infinity substitute).
- An alternative approach is through BFS, treating each amount as a node and each coin as an edge, but the DP method is more intuitive here.

Space & Time

Time Complexity: $O(\text{amount} * n)$ where n is the number of coins.

Space Complexity: $O(\text{amount})$ for the dp array.

Solution

We use a bottom-up dynamic programming approach. The idea is to use a one-dimensional dp array where each element at index x represents the minimum number of coins required to form the amount x . Starting from $dp[0]$ which is 0, we iterate through all amounts up to the target amount and update $dp[x]$ based on each coin denomination. If after filling the dp array the value $dp[\text{amount}]$ remains unchanged (i.e., greater than amount), it means the amount cannot be formed and we return -1.

#542 01 Matrix [Medium]

Key Insights

- Treat all 0s as starting points for a multi-source BFS.
- Update each neighboring cell's distance if a shorter distance is found.
- Utilize a queue to process cells in order of increasing distance.
- Ensure that each cell is processed only once by marking visited cells.

Space & Time

Time Complexity: $O(m \cdot n)$ since each cell is processed once.
Space Complexity: $O(m \cdot n)$ for the queue and the answer matrix.

Solution

We use a multi-source Breadth-First Search (BFS) where every 0 in the matrix is initially added to the BFS queue. Each neighboring cell that is a 1 will have its distance updated to be one plus the distance of the current cell if it hasn't been visited yet (or if a smaller distance is found). This ensures that the first time a 1 is reached, it is reached by the shortest path. Data structures used include a queue (or deque) for BFS and the matrix itself for storing distances.

#994 Rotting Oranges [Medium]

Key Insights

- Use Breadth-First Search (BFS) starting from all initially rotten oranges.
- Process the grid level by level, where each level represents one minute.
- Keep a count of fresh oranges and decrement it as they become rotten.
- If after the BFS there are still fresh oranges, then it is impossible to rot every orange.

Space & Time

Time Complexity: $O(m \cdot n)$ as every cell is processed at most once.
Space Complexity: $O(m \cdot n)$ in the worst case for the queue and auxiliary storage.

Solution

We begin by scanning the grid to locate all rotten oranges and count the fresh ones. These rotten oranges are added to a queue for a BFS. For each minute (BFS level), we process all the current rotten oranges and try to infect their adjacent fresh oranges. If an adjacent cell contains a fresh orange, we mark it rotten, add it to the queue, and decrement our fresh count. We continue this process level by level (minute by minute) until there are no fresh oranges left. If, after processing, there are still fresh oranges remaining, we return -1, indicating that not all oranges can become rotten.

#1197 Minimum Knight Moves [Medium]

Key Insights

- Leverage the symmetry of the chessboard by converting target coordinates to their absolute values.
- Use a Breadth-First Search (BFS) because all moves have equal weight, ensuring the first encounter with the target is the minimal path.
- Prune the search space by only considering positions that are likely beneficial (e.g., positions having coordinates not far less than -1).
- Track visited states to avoid redundant processing.
- Optimize by bounding the search region relative to the target distance.

Space & Time

Time Complexity: $O(n)$ where n is the number of positions processed during the BFS
Space Complexity: $O(n)$ due to the storage requirements for the BFS queue and the visited set

Solution

We solve the problem using a BFS starting from the origin. First, normalize the target by taking the absolute value of x and y . BFS is then applied by exploring all eight possible knight moves at each step. Each move generates a new position that is enqueued if it hasn't been visited and falls within a reasonable bound (e.g., coordinates ≥ -1). The search terminates as soon as the target position is reached.

#1730 Shortest Path to Get Food [Medium]

Key Insights

- Use Breadth-First Search (BFS) to explore the grid level by level.

- The BFS guarantees that when a food cell ('#') is reached, the current distance is the shortest.
- Maintain a visited structure to avoid re-processing the same cell.
- Consider boundary and obstacle ('X') conditions while traversing.

Space & Time

Time Complexity: $O(m * n)$, where m is the number of rows and n is the number of columns since each cell is processed at most once.

Space Complexity: $O(m * n)$ in the worst case due to the queue and visited matrix.

Solution

We use Breadth-First Search (BFS) starting from the cell marked with '*'. The BFS uses a queue to explore neighbors in the four allowed directions (up, down, left, right). Each level of BFS represents one step in the path. As soon as a cell containing food ('#') is reached, the current step count is returned. We also maintain a visited matrix to ensure that cells are not revisited, which could otherwise result in cycles or redundant processing. This approach ensures that the first time we encounter food, we have found the shortest possible path.

#127 Word Ladder [Hard]

Key Insights

- Use Breadth-First Search (BFS) to explore transformations level by level to guarantee the shortest path.
- Preprocess words by generating intermediate representations (e.g., replacing each letter with a wildcard) to quickly find neighbors.
- Use a visited set to avoid cycles.
- Each transformation counts as a level in the BFS, so the answer is the number of levels traversed.

Space & Time

Time Complexity: $O(N * M^2)$ where N is the number of words and M is the length of each word.

Space Complexity: $O(N * M)$ for the storage of intermediate mappings and the BFS queue.

Solution

We solve the problem using a BFS approach. First, we preprocess the wordList by creating a mapping of all possible intermediate states. For example, for the word "dog" and wildcard position, we generate "og", "d g", and "do*". This helps us find all adjacent words (neighbors) that are only one letter different in constant time. We then initialize a queue with the beginWord and initiate the BFS. For each word dequeued, we explore all valid transformations using the precomputed intermediate mapping. If the endWord is reached during this process, we return the current level (transformation sequence length). Otherwise, we continue the BFS until all possibilities are exhausted. If no valid transformation sequence is found, we return 0.

#317 Shortest Distance from All Buildings [Hard]

Key Insights

- We need to compute the Manhattan distance from each building (cell value 1) to all empty lands (cell value 0) by performing a BFS.
- Maintain two matrices: one for cumulative total distances and another for the count of buildings that reached a particular empty cell.
- Ensure that only those empty cells reachable by every building are considered.
- The ideal cell will have a reach count equal to the total number of buildings.
- If multiple buildings cannot all reach any specific empty cell, then return -1.

Space & Time

Time Complexity: $O(k * m * n)$ where k is the number of buildings and m, n are the grid dimensions.

Space Complexity: $O(m * n)$ due to the auxiliary matrices and visited state tracking used in BFS.

Solution

We first iterate through the grid to locate all buildings while counting them. For each building, we perform a BFS to compute the shortest distance to each reachable empty cell. During the BFS, we update the cumulative distance for

that cell and record that it was reached by one additional building. After processing all the buildings, we scan the grid to find the empty cell that is reachable from all buildings and has the minimum cumulative distance. If no such cell exists, we return -1.

#773 Sliding Puzzle [Hard]

Key Insights

- Represent the board as a string (e.g. "123450") to simplify state comparison and manipulation.
- Use Breadth First Search (BFS) to explore all possible moves since the puzzle has a small fixed state space ($6! = 720$ possible states).
- Precompute the valid neighbor indices for each board position to efficiently generate new states.
- Track visited states to avoid loops and redundant work.

Space & Time

Time Complexity: $O(1)$ in practice, since there are at most 720 states ($6!$ permutations).

Space Complexity: $O(1)$ for the same reason, as the state space is fixed and limited.

Solution

We solve the problem using a Breadth First Search (BFS) approach. The board configuration is flattened into a string to represent states. A mapping from each index to its possible neighbors (i.e., positions to which 0 can move) is precomputed. BFS is then used to explore every valid move from the initial state while marking states as visited to avoid cycles. When the goal state ("123450") is reached, we return the number of moves taken. If BFS completes without reaching the goal, the puzzle is unsolvable and we return -1.

#815 Bus Routes [Hard]

Key Insights

- Model the problem as a graph where nodes are bus routes.
- Two bus routes are connected if they share at least one common bus stop.
- Use a hash map to quickly look up bus routes available at any bus stop.
- Employ Breadth-First Search (BFS) on the bus routes graph to find the minimum number of bus transfers.
- Mark visited bus routes and bus stops to avoid redundant work.

Space & Time

Time Complexity: $O(N * L)$ in the worst-case scenario, where N is the number of bus routes and L is the average number of stops per route.

Space Complexity: $O(N * L)$ due to storage of the stop-to-buses mapping and BFS auxiliary data structures.

Solution

We begin by constructing a mapping from each bus stop to the list of buses passing through it. This allows quick retrieval of buses available at a given stop. Starting at the source stop, initialize the BFS queue with all buses that can be boarded at that stop. Then, for each bus route in the queue, inspect each stop along that route. If a stop is the target, return the number of buses taken so far. Otherwise, for each unvisited stop, add all adjacent bus routes (buses that pass through this stop) to the BFS queue with an incremented bus count. Continue until the queue is empty, which means the target cannot be reached.

EASY

Longest Common Prefix

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[String](#) · [Trie](#)

Lists: Grind 169

Problem:

Write a function to find the longest common prefix string amongst an array of strings.

If there is no common prefix, return an empty string "".

Example 1:

```
Input: strs = ["flower","flow","flight"]
Output: "fl"
```

Example 2:

```
Input: strs = ["dog","racecar","car"]
Output: ""
Explanation: There is no common prefix among the input strings.
```

Constraints:

- $1 \leq \text{strs.length} \leq 200$
- $0 \leq \text{strs}[i].\text{length} \leq 200$
- $\text{strs}[i]$ consists of only lowercase English letters if it is non-empty.

[*] Trie — Pattern Solution (stored optimal)

Python

```
def longestCommonPrefix(strs):
    # If no strings exist, return empty
    if not strs:
        return ""
    # Iterate over each index of the first string
    for i in range(len(strs[0])):
        current_char = strs[0][i]
        # Compare the current character with the corresponding one in the rest of the strings
        for s in strs[1:]:
            # If index exceeds length or characters differ, return the prefix found so far
            if i >= len(s) or s[i] != current_char:
                return strs[0][:i]
        # If no mismatch is found, return the complete first string
    return strs[0]

# Example usage:
print(longestCommonPrefix(["flower", "flow", "flight"]))
```

C++

```

#include <iostream>
#include <vector>
#include <string>
using namespace std;

string longestCommonPrefix(vector<string>& strs) {
    // Return empty string if array is empty
    if (strs.empty()) {
        return "";
    }

    // Loop over the first string's characters
    for (int i = 0; i < strs[0].size(); i++) {
        char currentChar = strs[0][i];
        // Compare currentChar with the same index in each other string
        for (int j = 1; j < strs.size(); j++) {
            // If index exceeds string length or characters mismatch, return the prefix
            if (i >= strs[j].size() || strs[j][i] != currentChar) {
                return strs[0].substr(0, i);
            }
        }
    }
    return strs[0];
}

Word Break

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [String](#) · [Dynamic Programming](#) · [Trie](#) · [Memoization](#)

Lists: Grind 169

Problem:

Given a string *s* and a dictionary of strings *wordDict*, return true if *s* can be segmented into a space-separated sequence of one or more dictionary words.

Note that the same word in the dictionary may be reused multiple times in the segmentation.

Example 1:

Input: *s* = "leetcode", *wordDict* = ["leet","code"]

Output: true

Explanation: Return true because "leetcode" can be segmented as "leet code".

Example 2:

Input: *s* = "applepenapple", *wordDict* = ["apple","pen"]

Output: true

Explanation: Return true because "applepenapple" can be segmented as "apple pen apple".

Note that you are allowed to reuse a dictionary word.

Example 3:

Input: `s = "catsandog"`, `wordDict = ["cats","dog","sand","and","cat"]`

Output: `false`

Constraints:

- `1 <= s.length <= 300`
- `1 <= wordDict.length <= 1000`
- `1 <= wordDict[i].length <= 20`
- `s` and `wordDict[i]` consist of only lowercase English letters.
- All the strings of `wordDict` are unique.

Implement Trie (Prefix Tree)

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Design](#) · [Trie](#)

Lists: Grind 169

Problem:

A trie (pronounced as "try") or prefix tree is a tree data structure used to efficiently store and retrieve keys in a dataset of strings. There are various applications of this data structure, such as autocomplete and spellchecker.

Implement the Trie class:

- `Trie()` Initializes the trie object.
- `void insert(String word)` Inserts the string word into the trie.
- `boolean search(String word)` Returns true if the string word is in the trie (i.e., was inserted before), and false otherwise.

- `boolean startsWith(String prefix)` Returns true if there is a previously inserted string word that has the prefix prefix, and false otherwise.

Example 1:

Input

```
["Trie", "insert", "search", "search", "startsWith", "insert", "search"]
[[], ["apple"], ["apple"], ["app"], ["app"], ["app"], ["app"]]
```

Output

```
[null, null, true, false, true, null, true]
```

Explanation

```
Trie trie = new Trie();
trie.insert("apple");
trie.search("apple"); // return True
trie.search("app"); // return False
trie.startsWith("app"); // return True
trie.insert("app");
trie.search("app"); // return True
```

Constraints:

- $1 \leq \text{word.length}, \text{prefix.length} \leq 2000$
- word and prefix consist only of lowercase English letters.
- At most $3 * 10^4$ calls in total will be made to insert, search, and startsWith.

Python

Python

```
class TrieNode:
    def __init__(self):
        # Dictionary to store child nodes and a flag for end of word.
        self.children = {}
        self.is_end_of_word = False

Design Add and Search Words Data Structure

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[String](#) · [DFS](#) · [Design](#) · [Trie](#)

Lists: Grind 169

Problem:

Design a data structure that supports adding new words and finding if a string matches any previously added string.

Implement the WordDictionary class:

- WordDictionary() Initializes the object.

- `void addWord(word)` Adds word to the data structure, it can be matched later.
- `bool search(word)` Returns true if there is any string in the data structure that matches word or false otherwise. word may contain dots '.' where dots can be matched with any letter.

Example:

Input

```
["WordDictionary", "addWord", "addWord", "addWord", "search", "search", "search", "search"]
[[], ["bad"], ["dad"], ["mad"], ["pad"], ["bad"], [".ad"], ["b.."]]
```

Output

```
[null, null, null, null, false, true, true, true]
```

Explanation

```
WordDictionary wordDictionary = new WordDictionary();
wordDictionary.addWord("bad");
wordDictionary.addWord("dad");
wordDictionary.addWord("mad");
wordDictionary.search("pad"); // return False
wordDictionary.search("bad"); // return True
wordDictionary.search(".ad"); // return True
wordDictionary.search("b.."); // return True
```

Constraints:

- $1 \leq \text{word.length} \leq 25$
- word in `addWord` consists of lowercase English letters.
- word in `search` consist of '.' or lowercase English letters.
- There will be at most 2 dots in word for search queries.
- At most 104 calls will be made to `addWord` and `search`.

Python

Python

```

class TrieNode:
    def __init__(self):
        # Dictionary to store child nodes
        self.children = {}
        # Flag to indicate if a word ends here
        self.is_end = False

class WordDictionary:
    def __init__(self):
        # Initialize the Trie with an empty root node
        self.root = TrieNode()

    def addWord(self, word: str) -> None:
        # Start at the root of the Trie
        node = self.root
        for char in word:
            # Create a new node if the character is not present
            if char not in node.children:
                node.children[char] = TrieNode()
            node = node.children[char]
        # Mark the end of the word
        node.is_end = True

    def search(self, word: str) -> bool:
        # DFS helper function

        def dfs(index, node):
            if index == len(word):
                return node.is_end
            char = word[index]
            if char == '.':
                # If wildcard, search all children nodes
                for child in node.children.values():
                    if dfs(index + 1, child):
                        return True
                return False
            else:
                # If character not found, word does not exist
                if char not in node.children:
                    return False
                return dfs(index + 1, node.children[char])
            return dfs(0, self.root)

# Example usage:
wd = WordDictionary()
wd.addWord("bad")
wd.addWord("dad")
wd.addWord("mad")
print(wd.search("pad")) # Output: False
print(wd.search("bad")) # Output: True
print(wd.search(".ad")) # Output: True

print(wd.search("b..")) # Output: True

Add Bold Tag in String

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [String](#) · [Trie](#)

Lists: Premium 98

Problem:

You are given a string *s* and an array of strings *words*.

You should add a closed pair of bold tag `<b>` and `</b>` to wrap the substrings in *s* that exist in *words*.

- If two such substrings overlap, you should wrap them together with only one pair of closed bold-tag.
- If two substrings wrapped by bold tags are consecutive, you should combine them.

Return *s* after adding the bold tags.

Example 1:

Input: *s* = "abcxyz123", *words* = ["abc","123"]

Output: "abcxyz123"

Explanation: The two strings of words are substrings of *s* as following: "abcxyz123".

We add `<b>` before each substring and `</b>` after each substring.

Example 2:

Input: s = "aaabbb", words = ["aa","b"]

Output: "aaabbb"

Explanation:

"aa" appears as a substring two times: "aaabbb" and "aaabbb".

"b" appears as a substring three times: "aaabbb", "aaabbb", and "aaabbb".

We add before each substring and after each substring:

"aaabbb".

Since the first two 's overlap, we merge them: "aaabbb".

Since now the four 's are consecutive, we merge them: "aaabbb".

Constraints:

- $1 \leq s.length \leq 1000$
- $0 \leq words.length \leq 100$
- $1 \leq words[i].length \leq 1000$
- s and words[i] consist of English letters and digits.
- All the values of words are unique.

Note: This question is the same as 758. Bold Words in String.

Python

```
# Brute Force Approach
class Solution:
    def addBoldTag(self, s, words):
        # Brute Force  $O(n \cdot m)$  - linear scan through all words
        matches = []
        for word in words:
            if word.startswith(prefix):
                matches.append(word)
        return matches
```

Python

Python

```

# Python Code Solution
def addBoldTag(s, words):
    n = len(s)
    # Mark positions to be bolded
    bold = [False] * n
    # Iterate each word and mark its occurrences
    for word in words:
        start = s.find(word)
        while start != -1:
            for i in range(start, start + len(word)):
                bold[i] = True
            start = s.find(word, start + 1)

    # Build the final result with bold tags
    result = []
    i = 0
    while i < n:
        if not bold[i]:
            result.append(s[i])
            i += 1
        else:
            result.append("<b>")
            while i < n and bold[i]:
                result.append(s[i])
                i += 1

            result.append("</b>")
    return "".join(result)

# Example usage:
# s = "abcxyz123"
# words = ["abc", "123"]
# print(addBoldTag(s, words)) # "<b>abc</b>xyz<b>123</b>"

# Line-by-line:
# 1. Initialize an array "bold" of length n to track which characters need bold formatting.
# 2. For each word, use string.find to locate every occurrence and mark the corresponding indices.
# 3. Traverse the string s. If the current character is marked bold and it is the start of a bold segment,
# insert the opening tag before appending characters until the end of that bold segment.
# 4. Append the closing tag after the bold segment and continue the process.

Top K Frequent Words

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Trie](#) · [Sorting](#) · [Heap](#)

Lists: Grind 169

Problem:

Given an array of strings words and an integer k, return the k most frequent strings.

Return the answer sorted by the frequency from highest to lowest. Sort the words with the same frequency by their lexicographical order.

Example 1:

Input: words = ["i","love","leetcode","i","love","coding"], k = 2

Output: ["i","love"]

Explanation: "i" and "love" are the two most frequent words.

Note that "i" comes before "love" due to a lower alphabetical order.

Example 2:

Input: words = ["the","day","is","sunny","the","the","the","sunny","is","is"], k = 4

Output: ["the","is","sunny","day"]

Explanation: "the", "is", "sunny" and "day" are the four most frequent words, with the number of occurrence being 4, 3, 2 and 1 respectively.

Constraints:

- $1 \leq \text{words.length} \leq 500$
- $1 \leq \text{words}[i].\text{length} \leq 10$
- words[i] consists of lowercase English letters.
- k is in the range [1, The number of unique words[i]]

Follow-up: Could you solve it in $O(n \log(k))$ time and $O(n)$ extra space?

>> Brute Force [Trie] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def topKFrequent(self, words, k):
        # Brute Force O(n*m) - linear scan through all words
        matches = []
        for word in words:
            if word.startswith(prefix):
                matches.append(word)
        return matches
```

Python

Python

```
import heapq
from collections import Counter

def topKFrequent(words, k):
    # Count the frequency of each word
    count = Counter(words)

    # Initialize a min-heap; Python's heapq is a min-heap.
    # The comparator is (frequency, negative word) but use word in reverse order:
    # Since we want words with lower alphabetical order to be prioritized in the result,
    # and in the min heap if frequencies equal, we want the one with lexicographically larger word to be
    popped.
    heap = []

    for word, freq in count.items():
        # Push each pair into the heap. The tuple ordering:
        # First element is frequency and second element is the word (with reverse lex order trick)
        heapq.heappush(heap, (freq, -ord(word[0]), word))
        # However, using -ord(word[0]) is not robust for multi-letter words.
        # Instead, we can use tuple (freq, word) with a custom comparator by ensuring we invert the word
        order by using word in reverse.
        # For simplicity, we push tuple (freq, word) and then pop if heap size > k with a custom condition.

    # Reset heap and use a custom comparator implemented by the tuple (-freq, word) to simulate max heap
    behavior.
    heap = []
    for word, freq in count.items():
        # We push with frequency as negative so that larger frequencies come first;

        # use word as is to satisfy lexicographical order when frequencies are equal.
        heapq.heappush(heap, (-freq, word))

    # Extract k elements from the heap and sort them accordingly.
    result = []
    for _ in range(k):
        freq, word = heapq.heappop(heap)
        result.append(word)
    return result

[*] Trie — Pattern Solution (stored optimal)

Python

```
import heapq
from collections import Counter

def topKFrequent(words, k):
    # Count the frequency of each word
    count = Counter(words)

    # Initialize a min-heap; Python's heapq is a min-heap.
    # The comparator is (frequency, negative word) but use word in reverse order:
    # Since we want words with lower alphabetical order to be prioritized in the result,
    # and in the min heap if frequencies equal, we want the one with lexicographically larger word to be
    # popped.
    heap = []

    for word, freq in count.items():
        # Push each pair into the heap. The tuple ordering:
        # First element is frequency and second element is the word (with reverse lex order trick)
        heapq.heappush(heap, (freq, -ord(word[0]), word))
        # However, using -ord(word[0]) is not robust for multi-letter words.
        # Instead, we can use tuple (freq, word) with a custom comparator by ensuring we invert the word
        # order by using word in reverse.
        # For simplicity, we push tuple (freq, word) and then pop if heap size > k with a custom condition.

    # Reset heap and use a custom comparator implemented by the tuple (-freq, word) to simulate max heap
    # behavior.
    heap = []
    for word, freq in count.items():
        # We push with frequency as negative so that larger frequencies come first;

        # use word as is to satisfy lexicographical order when frequencies are equal.
        heapq.heappush(heap, (-freq, word))

    # Extract k elements from the heap and sort them accordingly.
    result = []
    for _ in range(k):
        freq, word = heapq.heappop(heap)
        result.append(word)
    return result

# Example usage:
print(topKFrequent(["i", "love", "leetcode", "i", "love", "coding"], 2)) # Output: ['i', 'love']
```

C++

```

#include <iostream>
#include <vector>
#include <string>
#include <unordered_map>
#include <queue>
#include <functional>
#include <algorithm>
using namespace std;

vector<string> topKFrequent(vector<string>& words, int k) {
    // Count frequency of each word
    unordered_map<string, int> count;
    for (const auto& word : words)
        count[word]++;

    // Define a custom comparator for the min-heap.
    auto cmp = [](const pair<int, string>& a, const pair<int, string>& b) {
        // If frequencies are the same, compare lexicographically in reverse order
        if (a.first == b.first)
            return a.second < b.second;
        return a.first > b.first;
    };

    // Use a min-heap to keep top k elements
    priority_queue<pair<int, string>, vector<pair<int, string>>, decltype(cmp)> heap(cmp);

    for (auto& entry : count) {
        heap.push({entry.second, entry.first});
        if (heap.size() > (size_t) k)
            heap.pop();
    }

    // Extract words from the heap; they are in the reverse order.
    vector<string> result;
    while (!heap.empty()) {
        result.push_back(heap.top().second);
        heap.pop();
    }
    // Reverse the result list to have highest frequency first.
    reverse(result.begin(), result.end());
    return result;
}

// Example usage:
// int main() {
//     vector<string> words = {"i","love","leetcode","i","love","coding"};
//     int k = 2;
//     vector<string> ans = topKFrequent(words, k);
//     for (const string& word : ans)
//         cout << word << " ";

//     return 0;
// }

```

MEDIUM

Longest Word in Dictionary

Problem:

Given an array of strings `words` representing an English Dictionary, return the longest word in `words` that can be built one character at a time by other words in `words`.

If there is more than one possible answer, return the longest word with the smallest lexicographical order. If there is no answer, return the empty string.

Note that the word should be built from left to right with each additional character being added to the end of a previous word.

Example 1:

Input: `words = ["w","wo","wor","worl","world"]`

Output: `"world"`

Explanation: The word `"world"` can be built one character at a time by `"w"`, `"wo"`, `"wor"`, and `"worl"`.

Example 2:

Input: `words = ["a","banana","app","appl","ap","apply","apple"]`

Output: `"apple"`

Explanation: Both `"apply"` and `"apple"` can be built from other words in the dictionary. However, `"apple"` is lexicographically smaller than `"apply"`.

Constraints:

- $1 \leq \text{words.length} \leq 1000$
- $1 \leq \text{words}[i].\text{length} \leq 30$
- `words[i]` consists of lowercase English letters.

Design File System

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Design](#) · [Trie](#)

Lists: Denny Zhang

Problem:

You are asked to design a file system that allows you to create new paths and associate them with different values.

The format of a path is one or more concatenated strings of the form: / followed by one or more lowercase English letters. For example, "/leetcode" and "/leetcode/problems" are valid paths while an empty string "" and "/" are not.

Implement the FileSystem class:

- `bool createPath(string path, int value)` Creates a new path and associates a value to it if possible and returns true. Returns false if the path already exists or its parent path doesn't exist.
- `int get(string path)` Returns the value associated with path or returns -1 if the path doesn't exist.

Example 1:

```

Input:
["FileSystem","createPath","get"]
[[],["/a",1],["/a"]]
Output:
[null,true,1]
Explanation:
FileSystem fileSystem = new FileSystem();

fileSystem.createPath("/a", 1); // return true
fileSystem.get("/a"); // return 1

```

Example 2:

```

Input:
["FileSystem","createPath","createPath","get","createPath","get"]
[[],["/leet",1],["/leet/code",2],["/leet/code"],["/c/d",1],["/c"]]
Output:

```

```
[null,true,true,2,false,-1]
```

Explanation:

```
FileSystem fileSystem = new FileSystem();
```

```
fileSystem.createPath("/leet", 1); // return true
```

```
fileSystem.createPath("/leet/code", 2); // return true
```

```
fileSystem.get("/leet/code"); // return 2
```

```
fileSystem.createPath("/c/d", 1); // return false because the parent path "/c" doesn't exist.
```

```
fileSystem.get("/c"); // return -1 because this path doesn't exist.
```

Constraints:

- $2 \leq \text{path.length} \leq 100$
- $1 \leq \text{value} \leq 109$
- Each path is valid and consists of lowercase English letters and '/'.
- At most 104 calls in total will be made to createPath and get.

Python

Python

```
class FileSystem:
    def __init__(self):
        # Initialize hash map to store paths and their values.
        self.paths = {}

    def createPath(self, path: str, value: int) -> bool:
        # Check if the path already exists.
        if path in self.paths:
            return False

        # Find the index of the last '/' to get the parent path.
        last_slash = path.rfind('/')
        # If last_slash is 0, then parent is root level, which is invalid because "" is not a valid path.
        if last_slash == 0:
            parent = ""
        else:
            parent = path[:last_slash]

        # For non-root paths, the parent must exist.
        if parent and parent not in self.paths:
            return False

        # Store the new path with its value.
        self.paths[path] = value
        return True

    def get(self, path: str) -> int:
        # Return the value associated with the path, or -1 if it doesn't exist.
        return self.paths.get(path, -1)

# Example usage:
# fs = FileSystem()
# print(fs.createPath("/a", 1)) # True
# print(fs.get("/a")) # 1
```

Python

HARD

Word Search II

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [String](#) · [Backtracking](#) · [Trie](#) · [Matrix](#)

Lists: Grind 169

Problem:

Given an $m \times n$ board of characters and a list of strings words, return all words on the board.

Each word must be constructed from letters of sequentially adjacent cells, where adjacent cells are horizontally or vertically neighboring. The same letter cell may not be used more than once in a word.

Example 1:

o	a	a	n
e	t	a	e
i	h	k	r
i	f	l	v

Input: board = [["o","a","a","n"],["e","t","a","e"],["i","h","k","r"],["i","f","l","v"]], words = ["oath","pea","eat","rain"]
Output: ["eat","oath"]

Example 2:

a	b
c	d

Input: board = [["a","b"],["c","d"]], words = ["abcb"]
Output: []

Constraints:

- $m == \text{board.length}$
- $n == \text{board}[i].\text{length}$
- $1 \leq m, n \leq 12$
- $\text{board}[i][j]$ is a lowercase English letter.

- $1 \leq \text{words.length} \leq 3 \cdot 10^4$
- $1 \leq \text{words}[i].\text{length} \leq 10$
- $\text{words}[i]$ consists of lowercase English letters.
- All the strings of words are unique.

HARD

Palindrome Pairs

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [String](#) · [Trie](#)

Lists: Grind 169

Problem:

You are given a 0-indexed array of unique strings `words`.

A palindrome pair is a pair of integers (i, j) such that:

- $0 \leq i, j < \text{words.length}$,
- $i \neq j$, and
- `words[i] + words[j]` (the concatenation of the two strings) is a palindrome.

Return an array of all the palindrome pairs of words.

You must write an algorithm with $O(\sum \text{words}[i].\text{length})$ runtime complexity.

Example 1:

Input: `words = ["abcd","dcba","lls","s","sssll"]`

Output: `[[0,1],[1,0],[3,2],[2,4]]`

Explanation: The palindromes are `["abccddcba","dcbaabcd","slls","llsllsll"]`

Example 2:

Input: `words = ["bat","tab","cat"]`

Output: `[[0,1],[1,0]]`

Explanation: The palindromes are `["battab","tabbat"]`

Example 3:

Input: `words = ["a",""]`

Output: `[[0,1],[1,0]]`

Explanation: The palindromes are `["a","a"]`

Constraints:

- $1 \leq \text{words.length} \leq 5000$
- $0 \leq \text{words}[i].\text{length} \leq 300$
- `words[i]` consists of lowercase English letters.

HARD

Design In-Memory File System

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [String](#) · [Design](#) · [Trie](#)

Lists: Grind 169 | Premium 98

Problem:

Design a data structure that simulates an in-memory file system.

Implement the FileSystem class:

- `FileSystem()` Initializes the object of the system.
- `List<String> ls(String path)` If path is a file path, returns a list that only contains this file's name.
- If path is a directory path, returns the list of file and directory names in this directory.
- If filePath does not exist, creates that file containing given content.
- If filePath already exists, appends the given content to original content.

Example 1:

Operation	Output	Explanation
<code>FileSystem fs = new FileSystem()</code>	<code>null</code>	The constructor returns nothing.
<code>fs.ls("/")</code>	<code>[]</code>	Initially, directory <code>/</code> has nothing. So return empty list.
<code>fs.mkdir("/a/b/c")</code>	<code>null</code>	Create directory <code>a</code> in directory <code>/</code> . Then create directory <code>b</code> in directory <code>a</code> . Finally, create directory <code>c</code> in directory <code>b</code> .
<code>fs.addContentToFile("/a/b/c/d","hello")</code>	<code>null</code>	Create a file named <code>d</code> with content <code>"hello"</code> in directory <code>/a/b/c</code> .
<code>fs.ls("/")</code>	<code>["a"]</code>	Only directory <code>a</code> is in directory <code>/</code> .
<code>fs.readContentFromFile("/a/b/c/d")</code>	<code>"hello"</code>	Output the file content.

Input

```
["FileSystem", "ls", "mkdir", "addContentToFile", "ls", "readContentFromFile"]
[[], ["/"], ["/a/b/c"], ["/a/b/c/d", "hello"], ["/"], ["/a/b/c/d"]]
```

Output

```
[null, [], null, null, ["a"], "hello"]
```

Explanation

```
FileSystem fileSystem = new FileSystem();
fileSystem.ls("/"); // return []
fileSystem.mkdir("/a/b/c");
fileSystem.addContentToFile("/a/b/c/d", "hello");
fileSystem.ls("/"); // return ["a"]
fileSystem.readContentFromFile("/a/b/c/d"); // return "hello"
```

Constraints:

- `1 <= path.length, filePath.length <= 100`
- `path` and `filePath` are absolute paths which begin with `'/'` and do not end with `'/'` except that the path is just `'/'`.
- You can assume that all directory names and file names only contain lowercase letters, and the same names will not exist in the same directory.
- You can assume that all operations will be passed valid parameters, and users will not attempt to retrieve file content or list a directory or file that does not exist.
- You can assume that the parent directory for the file in `addContentToFile` will exist.
- `1 <= content.length <= 50`
- At most 300 calls will be made to `ls`, `mkdir`, `addContentToFile`, and `readContentFromFile`.

Design Search Autocomplete System

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[String](#) · [Design](#) · [Trie](#) · [Data Stream](#) · [Heap](#)

Lists: Premium 98

Problem:

Design a search autocomplete system for a search engine. Users may input a sentence (at least one word and end with a special character '#').

You are given a string array `sentences` and an integer array `times` both of length `n` where `sentences[i]` is a previously typed sentence and `times[i]` is the corresponding number of times the sentence was typed. For each input character except '#', return the top 3 historical hot sentences that have the same prefix as the part of the sentence already typed.

Here are the specific rules:

- The hot degree for a sentence is defined as the number of times a user typed the exactly same sentence before.
- The returned top 3 hot sentences should be sorted by hot degree (The first is the hottest one). If several sentences have the same hot degree, use ASCII-code order (smaller one appears first).
- If less than 3 hot sentences exist, return as many as you can.
- When the input is a special character, it means the sentence ends, and in this case, you need to return an empty list.

Implement the `AutocompleteSystem` class:

- `AutocompleteSystem(String[] sentences, int[] times)` Initializes the object with the sentences and times arrays.
- `List<String> input(char c)` This indicates that the user typed the character `c`. Returns an empty array `[]` if `c == '#'` and stores the inputted sentence in the system.
- Returns the top 3 historical hot sentences that have the same prefix as the part of the sentence already typed. If there are fewer than 3 matches, return them all.

Example 1:

Input

```
["AutocompleteSystem", "input", "input", "input", "input"]  
[[["i love you", "island", "iroman", "i love leetcode"], [5, 3, 2, 2]], ["i"], [" "], ["a"],  
["#"]]
```

Output

```
[null, ["i love you", "island", "i love leetcode"], ["i love you", "i love leetcode"], [],  
[]]
```

Explanation

```
AutocompleteSystem obj = new AutocompleteSystem(["i love you", "island", "iroman", "i love  
leetcode"], [5, 3, 2, 2]);  
obj.input("i"); // return ["i love you", "island", "i love leetcode"]. There are four  
sentences that have prefix "i". Among them, "ironman" and "i love leetcode" have same hot  
degree. Since ' ' has ASCII code 32 and 'r' has ASCII code 114, "i love leetcode" should be  
in front of "ironman". Also we only need to output top 3 hot sentences, so "ironman" will be  
ignored.  
obj.input(" "); // return ["i love you", "i love leetcode"]. There are only two sentences  
that have prefix "i ".  
obj.input("a"); // return []. There are no sentences that have prefix "i a".  
obj.input("#"); // return []. The user finished the input, the sentence "i a" should be saved  
as a historical sentence in system. And the following input will be counted as a new search.
```

Constraints:

- $n == \text{sentences.length}$
- $n == \text{times.length}$
- $1 \leq n \leq 100$
- $1 \leq \text{sentences}[i].\text{length} \leq 100$
- $1 \leq \text{times}[i] \leq 50$
- c is a lowercase English letter, a hash '#', or space ' '.
- Each tested sentence will be a sequence of characters c that end with the character '#'.
• Each tested sentence will have a length in the range $[1, 200]$.
• The words in each input sentence are separated by single spaces.
• At most 5000 calls will be made to input.

# print(auto.input("i"))
# print(auto.input(" "))
# print(auto.input("a"))
# print(auto.input("#"))

```

Quick Review — Trie 12 questions · insights · complexity · solution

#14 Longest Common Prefix [Easy]

Key Insights

- Compare characters of the strings one column at a time (vertical scanning).
- The longest possible prefix is limited by the length of the shortest string in the array.
- As soon as a mismatch is found, the prefix up to that point is the answer.
- Handle edge cases such as an empty input array or strings with no common prefix.

Space & Time

Time Complexity: $O(N \cdot M)$ where N is the number of strings and M is the length of the shortest string.

Space Complexity: $O(1)$ additional space (ignoring output space).

Solution

We use the vertical scanning approach:

– If the input array is empty, return an empty string. – Iterate character by character over the first string. – For each character, compare it with the corresponding character in each of the other strings. – If a mismatch or end of any string is encountered, return the substring from the start up to the current index. – If no mismatch is found, the entire first string is the common prefix.

This solution ensures that we only traverse the necessary part of the strings and stops early if a discrepancy is discovered.

#139 Word Break [Medium]

Key Insights

- Use Dynamic Programming (DP) to break the problem into subproblems.
- Create a DP array where $dp[i]$ is true if the substring $s[0:i]$ can be segmented using words from the dictionary.
- Leverage a hash set for fast look-up of dictionary words.
- For every index i , check all possible previous break points j such that $dp[j]$ is true and $s[j:i]$ is in the wordDict.
- The problem can also be approached with recursion and memoization, but DP is more straightforward for iterative implementation.

Space & Time

Time Complexity: $O(n^2)$ in the worst-case scenario, where n is the length of s (each substring check is $O(1)$ if using a hash set, and there could be $O(n^2)$ checks overall).

Space Complexity: $O(n)$ for the dp array and $O(k)$ for the hash set where k is the number of words in the dictionary.

Solution

The solution uses a Dynamic Programming (DP) approach:

– Convert wordDict to a hash set for constant time lookup. – Create a boolean dp array of size $n+1$ (n is the length of s), where $dp[i]$ indicates if $s[0:i]$ can be segmented. – Set $dp[0]$ to true because an empty string is always segmentable. – For each index i from 1 to n , iterate through all indices j from 0 to i : If $dp[j]$ is true and the substring $s[j:i]$ is in the dictionary, then set $dp[i]$ to true. Break early from the inner loop when a valid break is found. – Return $dp[n]$ as the result.

This method efficiently builds up the solution by utilizing previous results to determine if the entire string can be segmented.

#208 Implement Trie (Prefix Tree) [Medium]

Key Insights

- Use a tree-like structure where each node represents a character.
- Each node stores its children in a dictionary (or hash map) for $O(1)$ average time access.

- Mark the end of a word with a boolean flag.
- Insertion is done character by character, creating new nodes as needed.
- Searching and checking prefixes follow traversals down the tree.

Space & Time

Time Complexity:

- Insert: $O(m)$ where m is the length of the word.
- Search: $O(m)$
- startsWith: $O(m)$

Space Complexity:

- $O(N * M)$ in the worst-case scenario, where N is the number of words and M is the average length of the words, due to storing each character in the Trie.

Solution

We implement the Trie using a node-based approach. Each `TrieNode` contains a hash map (or dictionary) of its children and a boolean indicating if the node marks the end of a word. The `Trie` class uses these nodes to build out the words character by character. The `insert` method traverses and builds the necessary nodes; the `search` method verifies that all characters exist in order and that the final node marks the end of a word; the `startsWith` method checks if the prefix exists in the Trie. No tricky edge cases exist beyond handling null or empty inputs, as constraints guarantee valid lowercase strings.

#211 Design Add and Search Words Data Structure [Medium]

Key Insights

- Utilize a Trie (prefix tree) to efficiently store words.
- Each node in the Trie contains a dictionary for its children and a flag indicating the end of a word.
- The search operation is implemented with a depth-first search (DFS) approach.
- When the search query contains a dot, explore all possible child nodes.

Space & Time

Time Complexity:

- `addWord`: $O(w)$, where w is the length of the word.
- `search`: Worst-case $O(26^w)$ for words with multiple wildcards, but practical performance is better given constraints.

Space Complexity: $O(n * w)$, where n is the number of words and w is the average word length.

Solution

The `WordDictionary` is implemented using a Trie. For adding, we insert each character of the word into the Trie. For searching, we use DFS. When encountering a wildcard '.', we recursively search all children nodes. This structure combined with DFS efficiently addresses the wildcard matching and ensures good performance for multiple operations.

#616 Add Bold Tag in String [Medium]

Key Insights

- We need to identify every occurrence of each word in s .
- Overlapping or consecutive intervals should be merged to form one continuous bold region.
- Use an auxiliary data structure (e.g., a boolean array) to mark positions that should be bolded.
- Once the positions are marked, build the final string by inserting bold tags at the appropriate boundaries.

Space & Time

Time Complexity: $O(n * m * k)$ where n is the length of s , m is the number of words, and k is the average length of the words (due to substring matching).

Space Complexity: $O(n)$ for the auxiliary boolean array used to mark bold positions.

Solution

The solution involves two main steps:

– Identify and mark the indices in the string *s* that are part of any matching word. We do this by iterating over each word and marking every occurrence's start and end in a boolean array. – Construct the final string by traversing the boolean array. When encountering a segment of consecutive true values, wrap that segment with **and** tags.

The key idea is to merge intervals by marking every index that should be bold and then using a single pass to insert tags only when transitioning from non-bold to bold and vice versa.

#692 Top K Frequent Words [Medium]

Key Insights

- Count the frequency of each unique word using a hash table or dictionary.
- Use a min-heap (priority queue) to keep track of the top *k* frequent words. In the heap, the ordering is based on frequency; if frequencies are equal, order by lexicographical order (inverted condition for min-heap).
- Alternatively, you can sort the unique words based on frequency and lexicographical order and then pick the top *k*.
- For an efficient solution, use a min-heap that maintains size *k* achieving $O(n \log k)$ time complexity.

Space & Time

Time Complexity: $O(n \log k)$ when using a heap, where *n* is the number of unique words.

Space Complexity: $O(n)$ for storing the frequency counts and the heap.

Solution

We first calculate the frequency of each word using a hash table (or dictionary). Then, we use a min-heap that stores pairs of (frequency, word). The comparator for the heap is defined such that the root of the heap is the word with the smallest frequency; if two words have the same frequency, the word with the lexicographically larger value is considered "smaller" in our ordering so that it gets popped when the heap size exceeds *k*. After processing all words, the heap contains the top *k* frequent words. Finally, the heap elements are extracted and reversed (if needed) to produce the final list sorted from highest to lowest frequency with lexicographic tie-breaking.

#720 Longest Word in Dictionary [Medium]

Key Insights

- The word must be built character by character; hence every prefix (removing one character from the end at a time) must exist in the dictionary.
- Sorting the input list can help in ensuring that smaller words (prefixes) are processed first.
- Using a hash set to store valid words enables rapid prefix checks.
- Lexicographical order plays a role when words have the same length.

Space & Time

Time Complexity: $O(n * L + n \log n)$ where *n* is the number of words and *L* is the maximum length of a word ($n * L$ for prefix checking, and $n \log n$ for sorting).

Space Complexity: $O(n * L)$ for storing words in the set.

Solution

The approach begins by sorting the list of words. Sorting is done primarily by word length and secondarily by lexicographical order so that when we iterate through the words, all possible prefixes for a word have already been considered. Initialize a set to keep track of valid words that can be built one character at a time. For each word in the sorted list, check if all its prefixes (word without the last character progressively) exist in the set. If a word qualifies, add it to the set and check if it should be the new result based on length and lexicographical order. The set lookup ensures that checking each prefix is efficient.

#1166 Design File System [Medium]

Key Insights

- Use a data structure (like a hash map) to store paths and associated values.

- To create a new path, check that the path does not already exist.
- Ensure the immediate parent path exists before creation.
- When retrieving a value, simply look it up in the storage structure.
- Splitting the path by "/" allows easy identification of the parent.

Space & Time

Time Complexity:

- createPath: $O(n)$ per call where n is the number of segments in the path (to process and validate parent path).
- get: $O(1)$ per call if using a hash map.

Space Complexity: $O(m * L)$ where m is the number of paths stored and L is the average length of a path.

Solution

The solution uses a hash map (dictionary) to store file paths along with their associated values. For the createPath method, the algorithm:

- Checks if the path already exists.
 - Extracts the parent path by removing the last segment.
 - Validates the existence of the parent path.
 - Inserts the new path with its corresponding value if validation passes.
- For the get method, the algorithm simply returns the stored value if the path exists; otherwise, it returns -1 . This approach ensures efficient lookup and validation using string manipulation and hash map operations.

#212 Word Search II [Hard]

Key Insights

- Use Depth-First Search (DFS) to explore possible words starting from each board cell.
- Build a Trie (prefix tree) to store the words for $O(1)$ prefix checks and efficient pruning.
- Mark visited cells and restore them after DFS to avoid revisiting in the current search path.
- Prune search paths early if the current prefix is not part of any word in the Trie.

Space & Time

Time Complexity: $O(m * n * 4^L)$ in the worst case, where L is the maximum word length; however, using a Trie prunes unnecessary paths.

Space Complexity: $O(K)$ for the Trie storage, where K is the total number of letters in all words, plus $O(m * n)$ auxiliary space for recursion and board marking.

Solution

We first insert all words into a Trie data structure to allow quick lookups of prefixes. Then, for each cell in the board, we perform DFS. During DFS, if the current path matches a Trie node that represents a complete word, we add that word to the result list and mark it as found to avoid duplicates. We continue exploring adjacent cells (up, down, left, right) while marking the cell as visited. After exploring, we restore the original letter for further DFS calls. This combination of Trie and DFS with backtracking efficiently finds valid words on the board.

#336 Palindrome Pairs [Hard]

Key Insights

- A palindrome is a string that reads the same forwards and backwards.
- For any given word, if you split it into two parts, one part (either prefix or suffix) might be a palindrome.
- If the other part's reverse exists elsewhere in the array, then that reverse can be concatenated to yield a palindrome.
- Carefully handle edge cases like empty strings, since an empty string is a palindrome by default.

Space & Time

Time Complexity: $O(n * k^2)$ in the worst case where n is the number of words and k is the maximum word length, but with the palindrome checking optimized this can be considered $O(\text{sum of word lengths})$: Each word is processed once and each split is checked in $O(k)$ time.

Space Complexity: $O(n * k)$ due to the hashmap storing all words and their indices.

Solution

We use a hashmap (dictionary) to store each word and its corresponding index. For every word, we iterate through every possible split position to divide the word into a prefix and a suffix. For each split:

- If the prefix is a palindrome, we look for the reverse of the suffix in the hashmap. If found (and not the same word), then combining the reverse with the current word forms a palindrome.
- Similarly, if the suffix is a palindrome, we look for the reverse of the prefix.

We must be cautious with edge cases, especially when either part is empty, as the empty string is considered a palindrome. This method avoids checking every possible pair explicitly and leverages string reversal and palindrome checks to achieve efficiency.

#588 Design In-Memory File System [Hard]

Key Insights

- Use a tree (trie) to represent directories and files.
- Each node can be either a directory or a file; directories maintain a mapping of names to child nodes.
- For `ls`, if the given path is a file, return only its name. If it's a directory, return the sorted list of names of its children.
- `mkdir` must create all intermediate directories if they do not already exist.
- File nodes store content and support content appending.

Space & Time

Time Complexity:

- `ls`: $O(k \log k)$ where k is the number of entries in the directory (due to sorting), or $O(n)$ if traversing a long path.
- `mkdir`, `addContentToFile`, `readContentFromFile`: $O(d)$ where d is the depth of the file path.

Space Complexity:

- $O(T)$ where T is the total number of characters stored in directory names and file contents.

Solution

The solution uses a tree-based approach where each node represents either a directory or a file. Each directory node stores its children in a hash table (or dictionary) mapping names to node objects. File nodes store their content as a string and carry a flag indicating they are files. For the `ls` operation, check if the node is a file—if so, return its name; otherwise, list and sort the names of all children in that directory. The `mkdir` operation traverses (or creates) nodes for each segment of the provided path. The `addContentToFile` method accesses or creates the file node and appends the content. Finally, `readContentFromFile` retrieves the stored content from the file node.

#642 Design Search Autocomplete System [Hard]

Key Insights

- Use a Trie to efficiently store and retrieve sentences based on their prefixes.
- Maintain a mapping at each Trie node to record sentences (or their frequencies) that pass through that node.
- Use sorting or a min-heap to select the top three sentences based on their frequency (hot degree) and lexicographical order if frequencies tie.
- On receiving '#', update the Trie with the current sentence and reset the current search state.

Space & Time

Time Complexity: $O(L * \log k)$ per character input query, where L is the length of the current prefix and k is 3 (constant factor), thus ensuring efficient autocomplete.

Space Complexity: $O(N * L)$, where N is the number of unique sentences and L is the average sentence length, for maintaining the Trie.

Solution

The solution revolves around building a Trie where each node contains:

- A mapping to its child nodes.
- A hash map that records all sentences passing through the node along with their occurrence counts.

For each character entered (except '#'), the system:

- Traverses the Trie to find the current prefix node.
- Retrieves stored sentences at that node and sorts them based on the following criteria: descending by frequency and ascending lexicographically if frequencies are equal.
- Returns the top three sentences from the sorted result.

When the user inputs '#', the current sentence (tracked as user input so far) is added or its frequency updated in the Trie, and the input state resets.

Math

Lists: Grind 169

Problem:

Given an integer x , return true if x is a palindrome, and false otherwise.

Example 1:

Input: $x = 121$

Output: true

Explanation: 121 reads as 121 from left to right and from right to left.

Example 2:

Input: $x = -121$

Output: false

Explanation: From left to right, it reads -121. From right to left, it becomes 121-. Therefore it is not a palindrome.

Example 3:

Input: $x = 10$

Output: false

Explanation: Reads 01 from right to left. Therefore it is not a palindrome.

Constraints:

- $-231 \leq x \leq 231 - 1$

Follow up: Could you solve it without converting the integer to a string?

        if x < 0 || (x != 0 && x % 10 == 0) {
            return false;
        }
        let mut y = 0;
        while x > y {
            y = y * 10 + x % 10;
            x /= 10;
        }
        x == y || x == y / 10
    }
}
```

Rust

```
impl Solution {
    pub fn is_palindrome(mut x: i32) -> bool {
        if x < 0 || (x % 10 == 0 && x != 0) {
            return false;
        }
        let mut y = 0;
        while x > y {
            y *= 10;
            y += x % 10;
            x /= 10;
        }
        x == y || x == y / 10
    }
}
```

[*] Math — Pattern Solution (stored optimal)

Python

```
# Function to check if a number is a palindrome without converting to a string.
def isPalindrome(x):
    # Negative numbers and numbers ending with 0 (but not 0 itself) are not palindromic.
    if x < 0 or (x % 10 == 0 and x != 0):
        return False
    reversed_half = 0
    # Process: Reverse half of the number.
    while x > reversed_half:
        # Add the last digit of x to reversed_half.
        reversed_half = reversed_half * 10 + x % 10
        # Remove the last digit from x.
        x //= 10
    # For numbers with odd digits, reversed_half // 10 removes the middle digit.
    return x == reversed_half or x == reversed_half // 10

# Example usage:
print(isPalindrome(121)) # Output: True
print(isPalindrome(-121)) # Output: False
print(isPalindrome(10)) # Output: False
```

C++

```
// C++ solution to check if a number is a palindrome without converting it to a string.
class Solution {
public:
    bool isPalindrome(int x) {
        // Handle negative numbers and numbers ending in 0 (except 0 itself).
        if (x < 0 || (x % 10 == 0 && x != 0))
            return false;
        int reversedHalf = 0;
        // Reverse half of the number.
        while (x > reversedHalf) {
            // Append the last digit of x to reversedHalf.
            reversedHalf = reversedHalf * 10 + x % 10;
            // Remove the last digit from x.
            x /= 10;
        }
        // For odd-digit numbers, discard the middle digit by reversedHalf / 10.
        return x == reversedHalf || x == reversedHalf / 10;
    }
};
```

EASY

Roman to Integer

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Hash Table](#) · [Math](#) · [String](#)

Lists: Grind 169

Problem:

Roman numerals are represented by seven different symbols: I, V, X, L, C, D and M.

Symbol	Value
I	1
V	5
X	10
L	50
C	100
D	500
M	1000

For example, 2 is written as II in Roman numeral, just two ones added together. 12 is written as XII, which is simply X + II. The number 27 is written as XXVII, which is XX + V + II.

Roman numerals are usually written largest to smallest from left to right. However, the numeral for four is not IIII. Instead, the number four is written as IV. Because the one is before the five we subtract it making four. The same principle applies to the number nine, which is written as IX. There are six instances where subtraction is used:

- I can be placed before V (5) and X (10) to make 4 and 9.
- X can be placed before L (50) and C (100) to make 40 and 90.
- C can be placed before D (500) and M (1000) to make 400 and 900.

Given a roman numeral, convert it to an integer.

Example 1:

Input: s = "III"
Output: 3
Explanation: III = 3.

Example 2:

Input: s = "LVIII"
Output: 58
Explanation: L = 50, V = 5, III = 3.

Example 3:

Input: s = "MCMXCIV"
Output: 1994
Explanation: M = 1000, CM = 900, XC = 90 and IV = 4.

Constraints:

- $1 \leq s.length \leq 15$
- s contains only the characters ('I', 'V', 'X', 'L', 'C', 'D', 'M').
- It is guaranteed that s is a valid roman numeral in the range [1, 3999].

>> Brute Force [Math] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def romanToInt(self, s):
        # Brute Force - iterate all candidates
        for i in range(2, n + 1):
            is_valid = all(i % j != 0 for j in range(2, i))
            if is_valid: pass
        return 0
```

Python

Python

```
# Define a function to convert Roman numeral to integer
def romanToInt(s):
    # Map each Roman numeral to its integer value
    roman_values = {'I': 1, 'V': 5, 'X': 10, 'L': 50, 'C': 100, 'D': 500, 'M': 1000}
    total = 0 # Initialize the total integer value

    # Loop over the string using index
    for i in range(len(s)):
        # If this is not the last character and the current value is less than the next value,
        # subtract the current value; otherwise, add the current value.
        if i + 1 < len(s) and roman_values[s[i]] < roman_values[s[i + 1]]:
            total -= roman_values[s[i]]
        else:
            total += roman_values[s[i]]
    return total

# Example usage:
print(romanToInt("MCMXCIV")) # Output: 1994
```

Python

EASY

Confusing Number

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Math

Lists: Premium 98

Problem:

A confusing number is a number that when rotated 180 degrees becomes a different number with each digit valid.

We can rotate digits of a number by 180 degrees to form new digits.

- When 0, 1, 6, 8, and 9 are rotated 180 degrees, they become 0, 1, 9, 8, and 6 respectively.
- When 2, 3, 4, 5, and 7 are rotated 180 degrees, they become invalid.

Note that after rotating a number, we can ignore leading zeros.

- For example, after rotating 8000, we have 0008 which is considered as just 8.

Given an integer n , return true if it is a confusing number, or false otherwise.

Example 1:

6 $\xrightarrow{\text{rotate}}$ 9

Input: $n = 6$

Output: true

Explanation: We get 9 after rotating 6, 9 is a valid number, and $9 \neq 6$.

Example 2:

89 $\xrightarrow{\text{rotate}}$ 68

Input: $n = 89$

Output: true

Explanation: We get 68 after rotating 89, 68 is a valid number and $68 \neq 89$.

Example 3:

11 $\xrightarrow{\text{rotate}}$ 11

Input: $n = 11$

Output: false

Explanation: We get 11 after rotating 11, 11 is a valid number but the value remains the

same, thus 11 is not a confusing number

Constraints:

- $0 \leq n \leq 109$

Python

Python

```
# Define the mapping for valid rotations
def is_confusing_number(n: int) -> bool:
    rotation_map = {'0': '0', '1': '1', '6': '9', '8': '8', '9': '6'}

    # Convert the number to a string to process each digit
    original_str = str(n)
    rotated_str = ""

    # Process each digit in reverse order to simulate 180 degree rotation
    for digit in reversed(original_str):
        # If digit is not valid for rotation, return false immediately
        if digit not in rotation_map:
            return False
        # Append the rotated digit to the rotated string
        rotated_str += rotation_map[digit]

    # Convert rotated string to an integer (leading zeros are ignored)
    rotated_num = int(rotated_str)

    # The number is confusing if the rotated number is different from the original number
    return rotated_num != n

EASY

Missing Number in Arithmetic Progression

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Math](#)

Lists: Premium 98

Problem:

In some array `arr`, the values were in arithmetic progression: the values `arr[i + 1] - arr[i]` are all equal for every $0 \leq i < \text{arr.length} - 1$.

A value from `arr` was removed that was not the first or last value in the array.

Given `arr`, return the removed value.

Example 1:

Input: `arr = [5,7,11,13]`

Output: 9

Explanation: The previous array was `[5,7,9,11,13]`.

Example 2:

Input: `arr = [15,13,12]`

Output: 14

Explanation: The previous array was `[15,14,13,12]`.

Constraints:

- $3 \leq \text{arr.length} \leq 1000$
- $0 \leq \text{arr}[i] \leq 105$
- The given array is guaranteed to be a valid array.

Perform String Shifts

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Math](#) · [String](#)

Lists: Premium 98

Problem:

You are given a string *s* containing lowercase English letters, and a matrix *shift*, where *shift*[*i*] = [*directioni*, *amounti*]:

- *directioni* can be 0 (for left shift) or 1 (for right shift).
- *amounti* is the amount by which string *s* is to be shifted.
- A left shift by 1 means remove the first character of *s* and append it to the end.
- Similarly, a right shift by 1 means remove the last character of *s* and add it to the beginning.

Return the final string after all operations.

Example 1:

```
Input: s = "abc", shift = [[0,1],[1,2]]
Output: "cab"
Explanation:
[0,1] means shift to left by 1. "abc" -> "bca"
[1,2] means shift to right by 2. "bca" -> "cab"
```

Example 2:

```
Input: s = "abcdefg", shift = [[1,1],[1,1],[0,2],[1,3]]
Output: "efgabcd"
Explanation:
[1,1] means shift to right by 1. "abcdefg" -> "gabcdef"
[1,1] means shift to right by 1. "gabcdef" -> "fgabcde"
[0,2] means shift to left by 2. "fgabcde" -> "abcdefg"
[1,3] means shift to right by 3. "abcdefg" -> "efgabcd"
```

Constraints:

- $1 \leq s.length \leq 100$
- *s* only contains lower case English letters.
- $1 \leq shift.length \leq 100$
- $shift[i].length == 2$
- *directioni* is either 0 or 1.
- $0 \leq amounti \leq 100$

Reverse Integer

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Math

Lists: Grind 169

Problem:

Given a signed 32-bit integer x , return x with its digits reversed. If reversing x causes the value to go outside the signed 32-bit integer range $[-2^{31}, 2^{31} - 1]$, then return 0.

Assume the environment does not allow you to store 64-bit integers (signed or unsigned).

Example 1:

Input: $x = 123$

Output: 321

Example 2:

Input: $x = -123$

Output: -321

Example 3:

Input: $x = 120$

Output: 21

Constraints:

- $-231 \leq x \leq 231 - 1$

Python

Python

```
# Function to reverse an integer
def reverse(x: int) -> int:
    # Define the maximum and minimum limits for a 32-bit signed integer
    INT_MAX = 2**31 - 1
    INT_MIN = -2**31

    reversed_num = 0 # This will store the reversed number

    # Process each digit until x becomes 0
    while x != 0:
        # Pop the last digit from x
        # Use modulo 10 to get the last digit
        # For negative numbers, modulo may yield negative remainder
        pop = x % 10 if x > 0 else x % -10
        # Remove the last digit from x by integer division
        x = x // 10

        # Check if appending the digit would cause overflow
        if reversed_num > INT_MAX // 10 or (reversed_num == INT_MAX // 10 and pop > 7):
            return 0
        if reversed_num < INT_MIN // 10 or (reversed_num == INT_MIN // 10 and pop < -8):
            return 0

        # Append the digit to the reversed number
        reversed_num = reversed_num * 10 + pop

    return reversed_num

# Example usage:
print(reverse(123)) # Output: 321
print(reverse(-123)) # Output: -321
print(reverse(120)) # Output: 21
```

MEDIUM

Pow(x, n)

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Math](#) · [Recursion](#)

Lists: Grind 169

Problem:

Implement $\text{pow}(x, n)$, which calculates x raised to the power n (i.e., x^n).

Example 1:

Input: $x = 2.00000$, $n = 10$

Output: 1024.00000

Example 2:

Input: $x = 2.10000$, $n = 3$

Output: 9.26100

Example 3:

Input: $x = 2.00000$, $n = -2$

Output: 0.25000

Explanation: $2^{-2} = 1/2^2 = 1/4 = 0.25$

Constraints:

- $-100.0 < x < 100.0$
- $-231 \leq n \leq 231-1$
- n is an integer.
- Either x is not zero or $n > 0$.
- $-104 \leq x^n \leq 104$

Python

```
# Python implementation of pow(x, n) using exponentiation by squaring
def myPow(x, n):
    # if exponent is negative, invert x and make n positive
    if n < 0:
        x = 1 / x
        n = -n

    result = 1.0 # initialize result
    while n:
        # if the current exponent is odd, multiply result by the base
        if n % 2:
            result *= x
        x *= x # square the base for the next iteration
        n //= 2 # divide the exponent by 2
    return result

# Example usage:
print(myPow(2.0, 10)) # Output: 1024.0
print(myPow(2.1, 3)) # Output: 9.261000000000001
print(myPow(2.0, -2)) # Output: 0.25
```

[Array](#) · [Hash Table](#) · [Math](#) · [Design](#)

Lists: Grind 169

Problem:

Implement the RandomizedSet class:

- RandomizedSet() Initializes the RandomizedSet object.
- bool insert(int val) Inserts an item val into the set if not present. Returns true if the item was not present, false otherwise.
- bool remove(int val) Removes an item val from the set if present. Returns true if the item was present, false otherwise.
- int getRandom() Returns a random element from the current set of elements (it's guaranteed that at least one element exists when this method is called). Each element must have the same probability of being returned.

You must implement the functions of the class such that each function works in average O(1) time complexity.

Example 1:

Input

```
["RandomizedSet", "insert", "remove", "insert", "getRandom", "remove", "insert", "getRandom"]
[[], [1], [2], [2], [], [1], [2], []]
```

Output

```
[null, true, false, true, 2, true, false, 2]
```

Explanation

```
RandomizedSet randomizedSet = new RandomizedSet();
randomizedSet.insert(1); // Inserts 1 to the set. Returns true as 1 was inserted
successfully.
randomizedSet.remove(2); // Returns false as 2 does not exist in the set.
randomizedSet.insert(2); // Inserts 2 to the set, returns true. Set now contains [1,2].
randomizedSet.getRandom(); // getRandom() should return either 1 or 2 randomly.
randomizedSet.remove(1); // Removes 1 from the set, returns true. Set now contains [2].
randomizedSet.insert(2); // 2 was already in the set, so return false.
randomizedSet.getRandom(); // Since 2 is the only number in the set, getRandom() will always
return 2.
```

Constraints:

- $-231 \leq \text{val} \leq 231 - 1$
- At most $2 * 10^5$ calls will be made to insert, remove, and getRandom.
- There will be at least one element in the data structure when getRandom is called.

Python

Python

```
import random

class RandomizedSet:
    def __init__(self):
        # List to store the values
        self.values = []
        # Dictionary to map a value to its index in the list
        self.val_to_index = {}

    def insert(self, val: int) -> bool:
        # If the value is already present, do not insert.
        if val in self.val_to_index:
            return False
        # Append the value and store its index.
        self.val_to_index[val] = len(self.values)
        self.values.append(val)
        return True

    def remove(self, val: int) -> bool:
        # If the value is not present, return False.
        if val not in self.val_to_index:
            return False
        # Index of element to remove.
        index = self.val_to_index[val]
        # Get the last element.
```

```

        last_element = self.values[-1]

```

#1017

MEDIUM

Convert to Base -2

Math

Lists: Denny Zhang

Problem:

Given an integer n , return a binary string representing its representation in base -2 .

Note that the returned string should not have leading zeros unless the string is "0".

Example 1:

Input: $n = 2$
 Output: "110"
 Explanation: $(-2)^2 + (-2)^1 = 2$

Example 2:

Input: $n = 3$
 Output: "111"
 Explanation: $(-2)^2 + (-2)^1 + (-2)^0 = 3$

Example 3:

Input: $n = 4$
 Output: "100"
 Explanation: $(-2)^2 = 4$

Constraints:

- $0 \leq n \leq 109$

Python

Python

```
# Python solution with detailed comments
def baseNeg2(n: int) -> str:
    # Special case for zero as input.
    if n == 0:
        return "0"

    digits = [] # List to store digits in base -2.

    while n != 0:
        n, remainder = divmod(n, -2) # Get quotient and remainder when dividing by -2.
        if remainder < 0:
            # Adjust the remainder and increment the quotient.
            remainder += 2
            n += 1
        # Append the remainder (digit) to the list.
        digits.append(str(remainder))

    # Reverse the digits to form the proper binary string and return.
    return "".join(reversed(digits))

# Example usage:
print(baseNeg2(2)) # Output: "110"
print(baseNeg2(3)) # Output: "111"
print(baseNeg2(4)) # Output: "100"
```

Python

```

Find the Number of Distinct Colors Among the Balls

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Simulation](#)

Lists: [CodeSignal](#)

Problem:

You are given an integer limit and a 2D array queries of size $n \times 2$.

There are $\text{limit} + 1$ balls with distinct labels in the range $[0, \text{limit}]$. Initially, all balls are uncolored. For every query in queries that is of the form $[x, y]$, you mark ball x with the color y . After each query, you need to find the number of colors among the balls.

Return an array result of length n , where $\text{result}[i]$ denotes the number of colors after i th query.

Note that when answering a query, lack of a color will not be considered as a color.

Example 1:

Input: $\text{limit} = 4$, $\text{queries} = [[1,4],[2,5],[1,3],[3,4]]$

Output: $[1,2,2,3]$

Explanation:

- After query 0, ball 1 has color 4.
- After query 1, ball 1 has color 4, and ball 2 has color 5.
- After query 2, ball 1 has color 3, and ball 2 has color 5.
- After query 3, ball 1 has color 3, ball 2 has color 5, and ball 3 has color 4.

Example 2:

Input: limit = 4, queries = [[0,1],[1,2],[2,2],[3,4],[4,5]]

Output: [1,2,2,3,4]

Explanation:

- After query 0, ball 0 has color 1.
- After query 1, ball 0 has color 1, and ball 1 has color 2.
- After query 2, ball 0 has color 1, and balls 1 and 2 have color 2.
- After query 3, ball 0 has color 1, balls 1 and 2 have color 2, and ball 3 has color 4.
- After query 4, ball 0 has color 1, balls 1 and 2 have color 2, ball 3 has color 4, and ball 4 has color 5.

Constraints:

- $1 \leq \text{limit} \leq 109$
- $1 \leq n == \text{queries.length} \leq 105$
- $\text{queries}[i].\text{length} == 2$
- $0 \leq \text{queries}[i][0] \leq \text{limit}$
- $1 \leq \text{queries}[i][1] \leq 109$

Python

Python

```

# Python solution with detailed comments

def distinctColors(limit, queries):
    # Dictionary to keep track of the current color of each ball
    ball_color = {}
    # Dictionary to count the frequency of each color applied
    color_count = {}
    # List to store the results after each query
    results = []

    # Process each query one by one
    for ball, color in queries:
        # If the ball has been colored before, update the old color frequency
        if ball in ball_color:
            old_color = ball_color[ball]
            color_count[old_color] -= 1 # Decrement the count of the old color
            # If the frequency becomes zero, remove the color from the dictionary
            if color_count[old_color] == 0:
                del color_count[old_color]

        # Update ball's color to the new color
        ball_color[ball] = color
        # Increase the frequency count of the new color
        color_count[color] = color_count.get(color, 0) + 1

    # The number of distinct colors is the number of keys in color_count
    results.append(len(color_count))

    return results

# Example usage:
# limit = 4
# queries = [[1,4],[2,5],[1,3],[3,4]]
# print(distinctColors(limit, queries)) # Output: [1,2,2,3]

HARD

Text Justification

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [String](#) · [Simulation](#)

Lists: [CodeSignal](#)

Problem:

Given an array of strings words and a width maxWidth, format the text such that each line has exactly maxWidth characters and is fully (left and right) justified.

You should pack your words in a greedy approach; that is, pack as many words as you can in each line. Pad extra spaces ' ' when necessary so that each line has exactly maxWidth characters.

Extra spaces between words should be distributed as evenly as possible. If the number of spaces on a line does not divide evenly between words, the empty slots on the left will be assigned more spaces than the slots on the right.

For the last line of text, it should be left-justified, and no extra space is inserted between words.

Note:

- A word is defined as a character sequence consisting of non-space characters only.
- Each word's length is guaranteed to be greater than 0 and not exceed `maxWidth`.
- The input array `words` contains at least one word.

Example 1:

```
Input: words = ["This", "is", "an", "example", "of", "text", "justification."], maxWidth = 16
```

Output:

```
[
  "This   is   an",
  "example of text",
  "justification. "
]
```

Example 2:

```
Input: words = ["What","must","be","acknowledgment","shall","be"], maxWidth = 16
```

Output:

```
[
  "What   must   be",
  "acknowledgment ",
  "shall be      "
]
```

Explanation: Note that the last line is "shall be " instead of "shall be", because the last line must be left-justified instead of fully-justified.

Note that the second line is also left-justified because it contains only one word.

Example 3:

```
Input: words = ["Science","is","what","we","understand","well","enough","to","explain","to","a","computer.","Art","is","everything","else","we","do"], maxWidth = 20
```

Output:

```
[
  "Science is what we",
  "understand    well",
  "enough to explain to",
  "a computer. Art is",
  "everything else we",
  "do              "
]
```

Constraints:

- $1 \leq \text{words.length} \leq 300$
- $1 \leq \text{words}[i].\text{length} \leq 20$
- `words[i]` consists of only English letters and symbols.
- $1 \leq \text{maxWidth} \leq 100$
- $\text{words}[i].\text{length} \leq \text{maxWidth}$

'''
```

Explanation:

- The function `fullJustify` takes a list of words and a maximum width `maxWidth` as inputs.
- It iterates over each word, deciding whether to add the current word to the current line (`cur`) or to start a new line.
- If adding the current word to the line would exceed `maxWidth`, it justifies the current line by adding extra spaces between words as needed, then starts a new line.
- Once all words are processed, it left-justifies the last line by joining the remaining words in `cur` with a single space and then using `.ljust(maxWidth)` to ensure the line is of maximum width.
- The result is a list of strings, where each string represents a justified line of text.

This solution carefully handles edge cases, such as when there's only one word in the line (avoiding division by zero) and ensuring the last line is left-justified instead of fully justified.

Quick Review — Math 12 questions · insights · complexity · solution

#9 Palindrome Number [Easy]

Key Insights

- Negative numbers are not palindromic.
- A number ending in 0 (except 0 itself) cannot be a palindrome.
- Instead of reversing the entire number (risking overflow), reverse only half of the number and compare with the other half.
- For numbers with an odd number of digits, the middle digit can be disregarded.

Space & Time

Time Complexity: $O(\log_{10}(n))$ – Each iteration reduces the number by a factor of 10.

Space Complexity: $O(1)$ – Only constant extra space is used.

Solution

The solution checks for obvious non-palindrome cases first (negative numbers and numbers ending with 0 that are not 0). Then, it reverses half of the digits of the number while the original number is larger than the reversed half. Finally, it compares the remaining part of the original number with the reversed half. In the case of an odd number of digits, the middle digit is removed by dividing the reversed half by 10 before the final comparison.

#13 Roman to Integer [Easy]

Key Insights

- Map each Roman numeral character to its integer value using a hash table or dictionary.
- Loop through the string and check if the current numeral is less than the next numeral; if so, subtract its value.
- Otherwise, add its value to the total.
- This approach takes advantage of the subtractive notation used in Roman numerals.

Space & Time

Time Complexity: $O(n)$, where n is the length of the input string.

Space Complexity: $O(1)$, since the mapping and additional variables use constant space.

Solution

We use a dictionary (or hash map) to store the values of each Roman numeral. As we iterate over the string, we compare the current numeral's value with the next numeral's value. When a numeral of smaller value appears before a numeral of larger value, we subtract the current numeral's value; otherwise, we add it. This technique efficiently handles both the standard and subtractive cases in one pass through the string.

#504 Base 7 [Easy]

Key Insights

- Handle the edge case where num is 0.
- Use division and modulo operations to extract base 7 digits.
- Manage negative numbers by converting to positive and reattaching the minus sign.
- Build the base 7 digits in reverse order during iteration.

Space & Time

Time Complexity: $O(\log_7(n))$ where n is the absolute value of the number.

Space Complexity: $O(\log_7(n))$ to store the digits of the number.

Solution

The algorithm follows these steps:

- Check if num equals 0 and return "0".
- Determine if the number is negative. If so, work with its absolute value but remember the negative flag.
- Iteratively compute the remainder when divided by 7 (using modulo) and update the number by integer division by 7.
- Append each remainder (converted to character) to a list representing the digits.
- The digits are computed in reverse order; reverse the list for the correct order.
- If the original number was negative, append the "-" sign to the front.
- Join the digits to form the resulting base 7 string.

This approach uses basic arithmetic (division and modulo) and a list (or equivalent structure) to accumulate the computed digits.

#1056 Confusing Number [Easy]

Key Insights

- Use a mapping dictionary for valid rotations: {0:0, 1:1, 6:9, 8:8, 9:6}.
- Process the digits of n from right to left to form the rotated number.
- If any digit is not present in the mapping, the number is instantly not confusing.
- Compare the rotated number with the original number to check if they are different.

Space & Time

Time Complexity: $O(d)$, where d is the number of digits in n (approximately $O(\log n)$).

Space Complexity: $O(d)$, needed to store the rotated number string.

Solution

The approach is to convert the number to a string and iterate through it in reverse. For each digit, check if it is valid using the predefined mapping. If it is, append its rotated counterpart to a new string. After processing, convert the rotated string to an integer (ignoring any leading zeros). Finally, compare the rotated number to the original number. If they are different, the number is confusing.

#1228 Missing Number in Arithmetic Progression [Easy]

Key Insights

- The complete arithmetic progression has equal differences between consecutive numbers.
- The missing element can be found by calculating the expected common difference using the first and last elements.
- Since exactly one number is missing, iterate through the provided array to detect where the difference deviates from the expected common difference.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

We first compute the expected common difference (diff) for the original arithmetic progression. Since the actual progression had one more element than the current array, the formula used is: $\text{diff} = (\text{last element} - \text{first element}) / (n)$ where n is the length of the current array. Next, iterate over the array and check the difference between each pair of consecutive elements. When the actual difference deviates from diff, it indicates that the missing number is the previous element plus diff. This approach uses a simple loop and constant extra space.

#1427 Perform String Shifts [Easy]

Key Insights

- Consolidate all shifts by calculating a net shift: subtract for left shifts and add for right shifts.
- Use modulo arithmetic with the string length to avoid unnecessary full rotations.
- Slice the string based on the effective shift to construct the final string.

Space & Time

Time Complexity: $O(n + m)$, where n is the length of the string and m is the number of shift operations.

Space Complexity: $O(n)$ for the output string.

Solution

The solution involves computing the net shift value by iterating through the shift operations. Left shifts subtract from the net value, and right shifts add to the net value. After obtaining the cumulative shift, use modulo with the string length to normalize the shift, ensuring it lies within bounds. The final string is constructed by slicing the string into two parts and concatenating them appropriately. This approach leverages string slicing as the primary operation for shifting.

#7 Reverse Integer [Medium]

Key Insights

- The problem requires reversing the digits while preserving the sign.
- Watch out for integer overflow due to the reversed number exceeding the 32-bit signed integer limits.
- The approach involves repeatedly extracting the last digit from the number and appending it to a new reversed integer.
- Overflow checks are done during each iteration before actually appending the digit.

Space & Time

Time Complexity: $O(n)$, where n is the number of digits in the integer.

Space Complexity: $O(1)$, only constant extra space is used.

Solution

The solution uses a while loop to extract the last digit from the original number using modulo operation ($x \% 10$) and then removes this digit using integer division ($x //= 10$). A reversed number is constructed by multiplying the current reversed number by 10 and adding the extracted digit. Before appending each digit, the algorithm checks if the new reversed number will overflow a 32-bit signed integer by comparing it with the thresholds derived from `INT_MAX` and `INT_MIN`. The algorithm handles negative values by working with x directly since the modulo and division operations work properly with negatives in most languages.

#50 Pow(x, n) [Medium]

Key Insights

- Use exponentiation by squaring to reduce the number of multiplications.
- For a negative exponent, compute the power for $|n|$ and then take the reciprocal.
- Handle the edge case when n is 0 (return 1).
- The algorithm works in $O(\log n)$ time complexity.

Space & Time

Time Complexity: $O(\log |n|)$

Space Complexity: $O(1)$ for the iterative solution, or $O(\log |n|)$ if implemented recursively

Solution

We use exponentiation by squaring, an algorithm that reduces the number of multiplications by repeatedly squaring the base and halving the exponent. Here's how it works:

– If n is negative, switch x to $1/x$ and n to $-n$. – Initialize the result as 1. – Loop while n is greater than 0: If the current n is odd, multiply the result by x . Square the base x . Divide n by 2 (using integer division). This iterative approach efficiently computes the power in logarithmic steps. The same approach can be implemented recursively.

#380 Insert Delete GetRandom O(1) [Medium]

Key Insights

- Use a dynamic array (or list) to store the elements to allow $O(1)$ access by index.
- Use a hash table (or dictionary/map) to store the mapping from value to its index in the array.
- For removal, swap the element to be removed with the last element in the array, then delete the last element. This avoids expensive shifting of elements.
- `getRandom` can be implemented by generating a random index into the array.

Space & Time

Time Complexity: $O(1)$ on average for insert, remove, and getRandom operations.

Space Complexity: $O(n)$ where n is the number of elements stored in the data structure.

Solution

The solution involves maintaining a list to store the values and a hash map to quickly check for the presence of a value and to know its index in the list. When an element is removed, swap it with the last element of the list and update the map accordingly; then, remove the last element in $O(1)$ time. This approach ensures that insert, remove, and getRandom can all be achieved in constant time on average.

#1017 Convert to Base -2 [Medium]

Key Insights

- Use division and remainder operations to simulate converting a number to a different base.
- When working with a negative base (-2), the remainder can become negative; adjust the remainder (by adding the base's absolute value) and update the quotient accordingly.
- For $n = 0$, simply return "0" since there is nothing to convert.
- Build the answer by collecting digits (remainders) and then reversing the order since the conversion provides digits from least significant to most significant.

Space & Time

Time Complexity: $O(\log|n|)$ – the loop runs for about the number of digits in the base -2 representation.

Space Complexity: $O(\log|n|)$ – extra space for storing the computed digits.

Solution

To solve the problem, we simulate the conversion process similar to how you would convert an integer to a positive base. However, since the base here is -2 , special handling of negative remainders is needed. In each iteration, we:

- Divide the current number by -2 .
- Calculate the remainder. If the remainder is negative, adjust it by adding 2, and increment the quotient to compensate.
- Append the computed remainder to a list (which represents the binary digit).
- Continue until the number reduces to zero. Finally, reverse the list to form the correct string representation from the most significant to the least significant digit.

#3160 Find the Number of Distinct Colors Among the Balls [Medium]

Key Insights

- Use a hash map to store the current color of each ball that has been updated.
- Use another hash map to store how many balls currently use each color.
- When a ball is recolored, decrement the count of its old color first.
- If an old color count becomes zero, remove it from the color-frequency map.
- Add the new color to the ball and increment its frequency.
- After each query, the number of distinct colors is the number of keys in the color-frequency map.

Space & Time

Time Complexity: $O(q)$ average for q queries, since each query does only $O(1)$ average-time hash map work.

Space Complexity: $O(\min(q, n))$ for colored balls, plus $O(q)$ in the worst case for distinct active colors.

Solution

We solve the problem using two hash maps. The first map stores the current color of each ball, and the second map stores the frequency of each active color. For every query, if the ball already has a color, we decrement the old color's count and remove that color from the frequency map if its count reaches zero. Then we update the ball with the new color and increment the new color's frequency. After processing the query, the number of distinct colors is simply the number of keys remaining in the frequency map.

#68 Text Justification [Hard]

Key Insights

- Use a greedy approach to fill each line with as many words as possible without exceeding `maxWidth`.
- Calculate total space to distribute by subtracting the combined words length from `maxWidth`.
- If the line has more than one word, distribute extra spaces evenly; if not, pad the line with spaces at the end.
- Handle the last line separately by left-justifying the text (i.e., adding a single space between words and padding the end).

Space & Time

Time Complexity: $O(n)$ where n is the number of words, since each word is processed once.

Space Complexity: $O(n)$ for storing the result and temporary buffers.

Solution

The solution iterates over the list of words and groups them into lines such that the combined length of the words and minimum required spaces does not exceed `maxWidth`. For each completed group (line):

– If it's not the last line, calculate extra spaces required. – If the line has multiple words, distribute the spaces evenly, adding any extra spaces from left to right. – If the line contains a single word, append spaces to the right. – For the last line, join words with a single space and pad the remaining width with spaces.

Data structures used include lists (or arrays) for current words accumulation and the final result. The logic is implemented using a simulation approach to mimic text formatting.

#12 Arrays & Hashing — 18 questions · #12 of 21

#1

EASY

Two Sum

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#)

Lists: Grind 169

Problem:

Given an array of integers `nums` and an integer `target`, return indices of the two numbers such that they add up to `target`.

You may assume that each input would have exactly one solution, and you may not use the same element twice.

You can return the answer in any order.

Example 1:

Input: `nums = [2,7,11,15]`, `target = 9`

Output: `[0,1]`

Explanation: Because `nums[0] + nums[1] == 9`, we return `[0, 1]`.

Example 2:

Input: `nums = [3,2,4]`, `target = 6`

Output: `[1,2]`

Example 3:

Input: `nums = [3,3]`, `target = 6`

Output: `[0,1]`

Constraints:

- $2 \leq \text{nums.length} \leq 104$
- $-109 \leq \text{nums}[i] \leq 109$
- $-109 \leq \text{target} \leq 109$
- Only one valid answer exists.

Follow-up: Can you come up with an algorithm that is less than $O(n^2)$ time complexity?

Python

```
# Brute Force Approach
class Solution:
    def two_sum(self, nums, target):
        # Brute Force  $O(n^2)$  — check every pair;  $O(1)$  extra space
        for i in range(len(nums)):
            for j in range(i + 1, len(nums)):
                if nums[i] + nums[j] == target:
                    return [i, j]
```

Python

Python

```
def two_sum(nums, target):
    # Create a dictionary to store the number and its index
    num_to_index = {}
    # Iterate over the list with index
    for index, num in enumerate(nums):
        # Calculate the complement needed to reach the target
        complement = target - num
        # Check if the complement is in the dictionary
        if complement in num_to_index:
            # Return the index of the complement and the current index
            return [num_to_index[complement], index]
        # Store the number with its index
        num_to_index[num] = index
    # Since the problem guarantees one solution, we don't need a return statement here.

# Example usage:
# print(two_sum([2, 7, 11, 15], 9)) # Output: [0, 1]
```

Python

```

Missing Ranges

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Array

Lists: Premium 98

Problem:

You are given an inclusive range [lower, upper] and a sorted unique integer array nums, where all elements are within the inclusive range.

A number x is considered missing if x is in the range [lower, upper] and x is not in nums.

Return the shortest sorted list of ranges that exactly covers all the missing numbers. That is, no element of nums is included in any of the ranges, and each missing number is covered by one of the ranges.

Example 1:

Input: nums = [0,1,3,50,75], lower = 0, upper = 99

Output: [[2,2],[4,49],[51,74],[76,99]]

Explanation: The ranges are:

[2,2]

[4,49]

[51,74]

[76,99]

Example 2:

Input: nums = [-1], lower = -1, upper = -1

Output: []

Explanation: There are no missing ranges since there are no missing numbers.

Constraints:

- $-109 \leq \text{lower} \leq \text{upper} \leq 109$
- $0 \leq \text{nums.length} \leq 100$
- $\text{lower} \leq \text{nums}[i] \leq \text{upper}$
- All the values of nums are unique.

EASY

Moving Average from Data Stream

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Design](#) · [Queue](#) · [Data Stream](#)

Lists: Premium 98

Problem:

Given a stream of integers and a window size, calculate the moving average of all integers in the sliding window.

Implement the MovingAverage class:

- MovingAverage(int size) Initializes the object with the size of the window size.
- double next(int val) Returns the moving average of the last size values of the stream.

Example 1:

Input

```
["MovingAverage", "next", "next", "next", "next"]  
[[3], [1], [10], [3], [5]]
```

Output

```
[null, 1.0, 5.5, 4.66667, 6.0]
```

Explanation

```
MovingAverage movingAverage = new MovingAverage(3);  
movingAverage.next(1); // return 1.0 = 1 / 1  
movingAverage.next(10); // return 5.5 = (1 + 10) / 2  
movingAverage.next(3); // return 4.66667 = (1 + 10 + 3) / 3  
movingAverage.next(5); // return 6.0 = (10 + 3 + 5) / 3
```

Constraints:

- $1 \leq \text{size} \leq 1000$
- $-105 \leq \text{val} \leq 105$
- At most 104 calls will be made to next.

Python

Python

```
# Python solution for Moving Average from Data Stream  
  
from collections import deque # Import deque for efficient queue operations  
  
class MovingAverage:  
    def __init__(self, size):  
        # Initialize with the maximum window size  
        self.size = size # Maximum number of elements in the window  
        self.queue = deque() # Queue to store current window values  
        self.current_sum = 0 # Running sum of the current window  
  
    def next(self, val):  
        # Add new value to the window  
        if len(self.queue) == self.size:  
            # If the window is full, remove the oldest element and update the sum  
            removed_val = self.queue.popleft() # Remove the front element  
            self.current_sum -= removed_val # Subtract its value from the running sum  
        # Append the new value to the queue and update the sum  
        self.queue.append(val)  
        self.current_sum += val  
  
        # Calculate and return the moving average by dividing the running sum by the current window size  
        return self.current_sum / len(self.queue)
```

Find Anagram Mappings

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#)

Lists: Premium 98

Problem:

You are given two integer arrays `nums1` and `nums2` where `nums2` is an anagram of `nums1`. Both arrays may contain duplicates.

Return an index mapping array mapping from `nums1` to `nums2` where `mapping[i] = j` means the *i*th element in `nums1` appears in `nums2` at index *j*. If there are multiple answers, return any of them.

An array *a* is an anagram of an array *b* means *b* is made by randomizing the order of the elements in *a*.

Example 1:

Input: `nums1 = [12,28,46,32,50]`, `nums2 = [50,12,32,46,28]`

Output: `[1,4,3,2,0]`

Explanation: As `mapping[0] = 1` because the 0th element of `nums1` appears at `nums2[1]`, and `mapping[1] = 4` because the 1st element of `nums1` appears at `nums2[4]`, and so on.

Example 2:

Input: nums1 = [84,46], nums2 = [84,46]

Output: [0,1]

Constraints:

- $1 \leq \text{nums1.length} \leq 100$
- $\text{nums2.length} == \text{nums1.length}$
- $0 \leq \text{nums1}[i], \text{nums2}[i] \leq 105$
- nums2 is an anagram of nums1.

Counting Elements

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#)

Lists: Premium 98

Problem:

Given an integer array `arr`, count how many elements `x` there are, such that `x + 1` is also in `arr`. If there are duplicates in `arr`, count them separately.

Example 1:

Input: `arr = [1,2,3]`

Output: 2

Explanation: 1 and 2 are counted cause 2 and 3 are in `arr`.

Example 2:

Input: arr = [1,1,3,3,5,5,7,7]

Output: 0

Explanation: No numbers are counted, cause there is no 2, 4, 6, or 8 in arr.

Constraints:

- $1 \leq \text{arr.length} \leq 1000$
- $0 \leq \text{arr}[i] \leq 1000$

Count Good Triplets

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Enumeration](#)

Lists: [CodeSignal](#)

Problem:

Given an array of integers `arr`, and three integers `a`, `b` and `c`. You need to find the number of good triplets.

A triplet $(arr[i], arr[j], arr[k])$ is good if the following conditions are true:

- $0 \leq i < j < k < arr.length$
- $|arr[i] - arr[j]| \leq a$
- $|arr[j] - arr[k]| \leq b$
- $|arr[i] - arr[k]| \leq c$

Where $|x|$ denotes the absolute value of x .

Return the number of good triplets.

Example 1:

Input: `arr = [3,0,1,1,9,7]`, `a = 7`, `b = 2`, `c = 3`

Output: 4

Explanation: There are 4 good triplets: $[(3,0,1), (3,0,1), (3,1,1), (0,1,1)]$.

Example 2:

Input: arr = [1,1,2,2,3], a = 0, b = 0, c = 1

Output: 0

Explanation: No triplet satisfies all conditions.

Constraints:

- $3 \leq \text{arr.length} \leq 100$
- $0 \leq \text{arr}[i] \leq 1000$
- $0 \leq a, b, c \leq 1000$

MEDIUM

Insert Interval

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Array

Lists: Grind 169

Problem:

You are given an array of non-overlapping intervals where $\text{intervals}[i] = [\text{start}_i, \text{end}_i]$ represent the start and the end of the i th interval and intervals is sorted in ascending order by start_i . You are also given an interval $\text{newInterval} = [\text{start}, \text{end}]$ that represents the start and end of another interval.

Insert newInterval into intervals such that intervals is still sorted in ascending order by start_i and intervals still does not have any overlapping intervals (merge overlapping intervals if necessary).

Return intervals after the insertion.

Note that you don't need to modify intervals in-place. You can make a new array and return it.

Example 1:

Input: intervals = [[1,3],[6,9]], newInterval = [2,5]
Output: [[1,5],[6,9]]

Example 2:

Input: intervals = [[1,2],[3,5],[6,7],[8,10],[12,16]], newInterval = [4,8]
Output: [[1,2],[3,10],[12,16]]
Explanation: Because the new interval [4,8] overlaps with [3,5],[6,7],[8,10].

Constraints:

- $0 \leq \text{intervals.length} \leq 104$
- $\text{intervals}[i].\text{length} == 2$
- $0 \leq \text{start}_i \leq \text{end}_i \leq 105$
- intervals is sorted by start_i in ascending order.
- $\text{newInterval.length} == 2$
- $0 \leq \text{start} \leq \text{end} \leq 105$

MEDIUM

Product of Array Except Self

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Prefix Sum](#)

Lists: Grind 169

Problem:

Given an integer array `nums`, return an array `answer` such that `answer[i]` is equal to the product of all the elements of `nums` except `nums[i]`.

The product of any prefix or suffix of nums is guaranteed to fit in a 32-bit integer.

You must write an algorithm that runs in $O(n)$ time and without using the division operation.

Example 1:

Input: nums = [1,2,3,4]
Output: [24,12,8,6]

Example 2:

Input: nums = [-1,1,0,-3,3]
Output: [0,0,9,0,0]

Constraints:

- $2 \leq \text{nums.length} \leq 105$
- $-30 \leq \text{nums}[i] \leq 30$
- The input is generated such that $\text{answer}[i]$ is guaranteed to fit in a 32-bit integer.

Follow up: Can you solve the problem in $O(1)$ extra space complexity? (The output array does not count as extra space for space complexity analysis.)

[*] Arrays & Hashing — Pattern Solution (stored optimal)

Python

```

# Function to compute product of array except self
def productExceptSelf(nums):
    n = len(nums)
    # Initialize the output array with 1s for prefix multiplication
    answer = [1] * n

    # Compute prefix products: for each element answer[i] holds the product of all numbers left of i
    prefix_product = 1
    for i in range(n):
        answer[i] = prefix_product # store prefix product so far
        prefix_product *= nums[i] # update the prefix product

    # Compute suffix products and multiply with prefix products in answer array
    suffix_product = 1
    for i in range(n - 1, -1, -1):
        answer[i] *= suffix_product # multiply current answer with suffix product
        suffix_product *= nums[i] # update the suffix product

    return answer

# Example usage
nums = [1, 2, 3, 4]
print(productExceptSelf(nums)) # Output: [24, 12, 8, 6]

```

C++

```

// Function to compute product of array except self
#include <vector>
using namespace std;

vector<int> productExceptSelf(vector<int>& nums) {
    int n = nums.size();
    vector<int> answer(n, 1);

    // Compute prefix products and store in answer array
    int prefixProduct = 1;
    for (int i = 0; i < n; i++) {
        answer[i] = prefixProduct; // assigns product of all elements to the left of i
        prefixProduct *= nums[i]; // update prefix product for next iteration
    }

    // Compute suffix products and multiply into answer array
    int suffixProduct = 1;
    for (int i = n - 1; i >= 0; i--) {
        answer[i] *= suffixProduct; // update answer[i] with product of suffix elements
        suffixProduct *= nums[i]; // update suffix product
    }

    return answer;
}

// Example usage
// int main() {
//     vector<int> nums = {1, 2, 3, 4};
//     vector<int> result = productExceptSelf(nums);
//     // result should be [24, 12, 8, 6]
// }

Zigzag Iterator

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Design](#) · [Queue](#) · [Iterator](#)

Lists: Denny Zhang

Problem:

Given two vectors of integers `v1` and `v2`, implement an iterator to return their elements alternately.

Implement the `ZigzagIterator` class:

- `ZigzagIterator(List<int> v1, List<int> v2)` initializes the object with the two vectors `v1` and `v2`.
- `boolean hasNext()` returns true if the iterator still has elements, and false otherwise.
- `int next()` returns the current element of the iterator and moves the iterator to the next element.

Example 1:

Input: `v1 = [1,2]`, `v2 = [3,4,5,6]`

Output: `[1,3,2,4,5,6]`

Explanation: By calling `next` repeatedly until `hasNext` returns false, the order of elements returned by `next` should be: `[1,3,2,4,5,6]`.

Example 2:

Input: `v1 = [1]`, `v2 = []`

Output: `[1]`

Example 3:

Input: `v1 = []`, `v2 = [1]`

Output: `[1]`

Constraints:

- $0 \leq v1.length, v2.length \leq 1000$
- $1 \leq v1.length + v2.length \leq 2000$
- $-231 \leq v1[i], v2[i] \leq 231 - 1$

Follow up: What if you are given `k` vectors? How well can your code be extended to such cases?

Clarification for the follow-up question:

The "Zigzag" order is not clearly defined and is ambiguous for $k > 2$ cases. If "Zigzag" does not look right to you, replace "Zigzag" with "Cyclic".

Follow-up Example:

Input: `v1 = [1,2,3]`, `v2 = [4,5,6,7]`, `v3 = [8,9]`

Output: `[1,4,8,2,5,9,3,6,7]`

Python

[Python](#)

```

class ZigzagIterator:
    def __init__(self, v1, v2):
        # Initialize the queue with non-empty vectors paired with starting index 0
        from collections import deque
        self.queue = deque()
        if v1:
            self.queue.append((v1, 0))
        if v2:
            self.queue.append((v2, 0))

    def next(self):
        # Pop from the left
        vec, idx = self.queue.popleft()
        result = vec[idx]
        # If there are more elements, put it back with the next index
        if idx + 1 < len(vec):
            self.queue.append((vec, idx + 1))
        return result

    def hasNext(self):
        return len(self.queue) > 0

# Example usage:

MEDIUM

Range Sum Query – Mutable

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Design](#) · [Binary Indexed Tree](#) · [Segment Tree](#)

Lists: Denny Zhang

Problem:

Given an integer array `nums`, handle multiple queries of the following types:

1. Update the value of an element in `nums`.
2. Calculate the sum of the elements of `nums` between indices `left` and `right` inclusive where `left ≤ right`.

Implement the `NumArray` class:

- `NumArray(int[] nums)` Initializes the object with the integer array `nums`.
- `void update(int index, int val)` Updates the value of `nums[index]` to be `val`.
- `int sumRange(int left, int right)` Returns the sum of the elements of `nums` between indices `left` and `right` inclusive (i.e. `nums[left] + nums[left + 1] + ... + nums[right]`).

Example 1:

Input

```
["NumArray", "sumRange", "update", "sumRange"]
[[[1, 3, 5]], [0, 2], [1, 2], [0, 2]]
```

Output

```
[null, 9, null, 8]
```

Explanation

```
NumArray numArray = new NumArray([1, 3, 5]);
numArray.sumRange(0, 2); // return 1 + 3 + 5 = 9
numArray.update(1, 2); // nums = [1, 2, 5]
numArray.sumRange(0, 2); // return 1 + 2 + 5 = 8
```

Constraints:

- $1 \leq \text{nums.length} \leq 3 * 10^4$
- $-100 \leq \text{nums}[i] \leq 100$
- $0 \leq \text{index} < \text{nums.length}$
- $-100 \leq \text{val} \leq 100$
- $0 \leq \text{left} \leq \text{right} < \text{nums.length}$
- At most $3 * 10^4$ calls will be made to update and sumRange.

Python

Python

```
# Python implementation using a Binary Indexed Tree (Fenwick Tree)
class NumArray:
    def __init__(self, nums):
        # Store the original array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#)

Lists: [CodeSignal](#)

Problem:

Given four integer arrays `nums1`, `nums2`, `nums3`, and `nums4` all of length `n`, return the number of tuples (i, j, k, l) such that:

- $0 \leq i, j, k, l < n$
- $nums1[i] + nums2[j] + nums3[k] + nums4[l] == 0$

Example 1:

Input: `nums1 = [1,2]`, `nums2 = [-2,-1]`, `nums3 = [-1,2]`, `nums4 = [0,2]`

Output: 2

Explanation:

The two tuples are:

1. $(0, 0, 0, 1) \rightarrow nums1[0] + nums2[0] + nums3[0] + nums4[1] = 1 + (-2) + (-1) + 2 = 0$
2. $(1, 1, 0, 0) \rightarrow nums1[1] + nums2[1] + nums3[0] + nums4[0] = 2 + (-1) + (-1) + 0 = 0$

Example 2:

Input: `nums1 = [0]`, `nums2 = [0]`, `nums3 = [0]`, `nums4 = [0]`

Output: 1

Constraints:

- $n == nums1.length$
- $n == nums2.length$
- $n == nums3.length$
- $n == nums4.length$
- $1 \leq n \leq 200$
- $-228 \leq nums1[i], nums2[i], nums3[i], nums4[i] \leq 228$

MEDIUM

Contiguous Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Prefix Sum](#)

Lists: Grind 169

Problem:

Given a binary array `nums`, return the maximum length of a contiguous subarray with an equal number of 0 and 1.

Example 1:

Input: `nums = [0,1]`

Output: 2

Explanation: `[0, 1]` is the longest contiguous subarray with an equal number of 0 and 1.

Example 2:

Input: `nums = [0,1,0]`

Output: 2

Explanation: `[0, 1]` (or `[1, 0]`) is a longest contiguous subarray with equal number of 0 and 1.

Example 3:

Input: `nums = [0,1,1,1,1,1,0,0,0]`

Output: 6

Explanation: `[1,1,1,0,0,0]` is the longest contiguous subarray with equal number of 0 and 1.

Constraints:

- $1 \leq \text{nums.length} \leq 105$
- `nums[i]` is either 0 or 1.

Subarray Sum Equals K

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Prefix Sum](#)

Lists: Grind 169

Problem:

Given an array of integers `nums` and an integer `k`, return the total number of subarrays whose sum equals to `k`.

A subarray is a contiguous non-empty sequence of elements within an array.

Example 1:

Input: `nums = [1,1,1]`, `k = 2`

Output: 2

Example 2:

Input: `nums = [1,2,3]`, `k = 3`

Output: 2

Constraints:

- $1 \leq \text{nums.length} \leq 2 * 10^4$
- $-1000 \leq \text{nums}[i] \leq 1000$
- $-10^7 \leq k \leq 10^7$

Pairs of Songs With Total Durations Divisible by 60

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Counting](#)

Lists: [CodeSignal](#)

Problem:

You are given a list of songs where the i th song has a duration of $\text{time}[i]$ seconds.

Return the number of pairs of songs for which their total duration in seconds is divisible by 60.

Formally, we want the number of indices i, j such that $i < j$ with $(\text{time}[i] + \text{time}[j]) \% 60 == 0$.

Example 1:

Input: time = [30,20,150,100,40]

Output: 3

Explanation: Three pairs have a total duration divisible by 60:

(time[0] = 30, time[2] = 150): total duration 180

(time[1] = 20, time[3] = 100): total duration 120

(time[1] = 20, time[4] = 40): total duration 60

Example 2:

Input: time = [60,60,60]

Output: 3

Explanation: All three pairs have a total duration of 120, which is divisible by 60.

Constraints:

- $1 \leq \text{time.length} \leq 6 * 10^4$
- $1 \leq \text{time}[i] \leq 500$

    pub fn num_pairs_divisible_by60(time: Vec<i32>) -> i32 {
        let mut cnt = [0i32; 60];
        let mut ans: i32 = 0;
        for mut x in time {
            x %= 60;
            let y = (60 - x) % 60;
            ans += cnt[y as usize];
            cnt[x as usize] += 1;
        }
        ans
    }
}
```

Rust

```
impl Solution {
    pub fn num_pairs_divisible_by60(time: Vec<i32>) -> i32 {
        let mut cnt = [0i32; 60];
        let mut ans: i32 = 0;
        for mut x in time {
            x %= 60;
            let y = (60 - x) % 60;
            ans += cnt[y as usize];
            cnt[x as usize] += 1;
        }
        ans
    }
}
```

[*] Arrays & Hashing — Pattern Solution (matched from community answers)

Python

```
class Solution:
    def numPairsDivisibleBy60(self, time: List[int]) -> int:
        cnt = Counter()
        ans = 0
        for x in time:
            x %= 60
            y = (60 - x) % 60
            ans += cnt[y]
            cnt[x] += 1
        return ans

MEDIUM

Remove Interval

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

Array

Lists: Premium 98

Problem:

A set of real numbers can be represented as the union of several disjoint intervals, where each interval is in the form $[a, b)$. A real number x is in the set if one of its intervals $[a, b)$ contains x (i.e. $a \leq x < b$).

You are given a sorted list of disjoint intervals representing a set of real numbers as described above, where $\text{intervals}[i] = [a_i, b_i]$ represents the interval $[a_i, b_i)$. You are also given another interval toBeRemoved .

Return the set of real numbers with the interval toBeRemoved removed from intervals . In other words, return the set of real numbers such that every x in the set is in intervals but not in toBeRemoved . Your answer should be a sorted list of disjoint intervals as described above.

Example 1:

Input: $\text{intervals} = [[0, 2], [3, 4], [5, 7]]$, $\text{toBeRemoved} = [1, 6]$

Output: $[[0, 1], [6, 7]]$

Example 2:

Input: intervals = [[0,5]], toBeRemoved = [2,3]
Output: [[0,2],[3,5]]

Example 3:

Input: intervals = [[-5,-4],[-3,-2],[1,2],[3,5],[8,9]], toBeRemoved = [-1,4]
Output: [[-5,-4],[-3,-2],[4,5],[8,9]]

Constraints:

- $1 \leq \text{intervals.length} \leq 104$
- $-109 \leq a_i < b_i \leq 109$

First Unique Number

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Design](#) · [Queue](#) · [Data Stream](#)

Lists: Premium 98

Problem:

You have a queue of integers, you need to retrieve the first unique integer in the queue.

Implement the FirstUnique class:

- `FirstUnique(int[] nums)` Initializes the object with the numbers in the queue.

- `int showFirstUnique()` returns the value of the first unique integer of the queue, and returns `-1` if there is no such integer.
- `void add(int value)` insert value to the queue.

Example 1:

```

Input:
["FirstUnique","showFirstUnique","add","showFirstUnique","add","showFirstUnique","add","showFirstUnique"]
[[[2,3,5]],[],[5],[],[2],[],[3],[]]
Output:
[null,2,null,2,null,3,null,-1]
Explanation:
FirstUnique firstUnique = new FirstUnique([2,3,5]);
firstUnique.showFirstUnique(); // return 2
firstUnique.add(5); // the queue is now [2,3,5,5]
firstUnique.showFirstUnique(); // return 2
firstUnique.add(2); // the queue is now [2,3,5,5,2]
firstUnique.showFirstUnique(); // return 3
firstUnique.add(3); // the queue is now [2,3,5,5,2,3]
firstUnique.showFirstUnique(); // return -1

```

Example 2:

```

Input:
["FirstUnique","showFirstUnique","add","add","add","add","add","showFirstUnique"]
[[[7,7,7,7,7,7]],[],[7],[3],[3],[7],[17],[]]
Output:
[null,-1,null,null,null,null,null,17]
Explanation:
FirstUnique firstUnique = new FirstUnique([7,7,7,7,7,7]);
firstUnique.showFirstUnique(); // return -1
firstUnique.add(7); // the queue is now [7,7,7,7,7,7,7]
firstUnique.add(3); // the queue is now [7,7,7,7,7,7,7,3]
firstUnique.add(3); // the queue is now [7,7,7,7,7,7,7,3,3]
firstUnique.add(7); // the queue is now [7,7,7,7,7,7,7,3,3,7]
firstUnique.add(17); // the queue is now [7,7,7,7,7,7,7,3,3,7,17]
firstUnique.showFirstUnique(); // return 17

```

Example 3:

```

Input:
["FirstUnique","showFirstUnique","add","showFirstUnique"]
[[[809]],[],[809],[]]
Output:
[null,809,null,-1]
Explanation:
FirstUnique firstUnique = new FirstUnique([809]);
firstUnique.showFirstUnique(); // return 809
firstUnique.add(809); // the queue is now [809,809]
firstUnique.showFirstUnique(); // return -1

```

Constraints:

- $1 \leq \text{nums.length} \leq 10^5$
- $1 \leq \text{nums}[i] \leq 10^8$

- $1 \leq \text{value} \leq 10^8$
- At most 50000 calls will be made to showFirstUnique and add.

Python

Python

```
import collections

class FirstUnique:
    # Initialize the object with the numbers in the queue.
    def __init__(self, nums):
        # Using deque for efficient popleft operations.
        self.queue = collections.deque()
        # Dictionary to store frequency count.
        self.count = collections.defaultdict(int)

Find Occurrences of an Element in an Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#)

Lists: [CodeSignal](#)

Problem:

You are given an integer array `nums`, an integer array `queries`, and an integer `x`.

For each `queries[i]`, you need to find the index of the `queries[i]`th occurrence of `x` in the `nums` array.

If there are fewer than `queries[i]` occurrences of `x`, the answer should be `-1` for that query.

Return an integer array `answer` containing the answers to all queries.

Example 1:

Input: `nums = [1,3,1,7]`, `queries = [1,3,2,4]`, `x = 1`

Output: `[0,-1,2,-1]`

Explanation:

- For the 1st query, the first occurrence of 1 is at index 0.
- For the 2nd query, there are only two occurrences of 1 in `nums`, so the answer is `-1`.
- For the 3rd query, the second occurrence of 1 is at index 2.
- For the 4th query, there are only two occurrences of 1 in `nums`, so the answer is `-1`.

Example 2:

Input: nums = [1,2,3], queries = [10], x = 5

Output: [-1]

Explanation:

- For the 1st query, 5 doesn't exist in nums, so the answer is -1.

Constraints:

- $1 \leq \text{nums.length}, \text{queries.length} \leq 105$
- $1 \leq \text{queries}[i] \leq 105$
- $1 \leq \text{nums}[i], x \leq 104$

Python

Python

```
# Function to find occurrences of x at specified query indices
def find_occurrences(nums, queries, x):
    # Precompute the indices where x occurs in nums
    positions = []
    for index, num in enumerate(nums):
        if num == x:
            positions.append(index)

    # Process each query
    results = []
    for occurrence in queries:
        # Check if the requested occurrence exists
        if occurrence <= len(positions):
            results.append(positions[occurrence - 1]) # Convert to zero-based index
        else:
            results.append(-1)
    return results

# Example usage:
nums = [1, 3, 1, 7]
queries = [1, 3, 2, 4]
x = 1
print(find_occurrences(nums, queries, x)) # Output: [0, -1, 2, -1]

First Missing Positive

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Hash Table](#)

Lists: Grind 169

Problem:

Given an unsorted integer array `nums`. Return the smallest positive integer that is not present in `nums`.

You must implement an algorithm that runs in $O(n)$ time and uses $O(1)$ auxiliary space.

Example 1:

Input: `nums = [1,2,0]`

Output: 3

Explanation: The numbers in the range `[1,2]` are all in the array.

Example 2:

Input: `nums = [3,4,-1,1]`

Output: 2

Explanation: 1 is in the array but 2 is missing.

Example 3:

Input: `nums = [7,8,9,11,12]`

Output: 1

Explanation: The smallest positive integer 1 is missing.

Constraints:

- $1 \leq \text{nums.length} \leq 105$
- $-231 \leq \text{nums}[i] \leq 231 - 1$

#1 Two Sum [Easy]

Key Insights

- Use a hash table to store the elements and their indices for fast lookup.
- For each element, calculate its complement: target minus the current element.
- Check if the complement exists in the hash table.
- If found, return the indices of the current element and its complement.
- This approach only requires a single pass through the array.

Space & Time

Time Complexity: $O(n)$ – We traverse the list only once.

Space Complexity: $O(n)$ – In the worst-case, we store all elements in the hash table.

Solution

We use a hash table (dictionary) to map each array element to its index as we iterate. For each number, we compute the complement (target – number) and check if it already exists in our hash table. If the complement is found, we return the indices. This one-pass solution ensures linear time complexity and avoids the need for nested loops.

#163 Missing Ranges [Easy]

Key Insights

- Use a pointer (or iterate index) to traverse the nums array while keeping track of the previous number considered.
- Check for missing numbers before the first element, between consecutive elements, and after the last element.
- When a gap is found, convert it to a range string that is either a single number (if the gap is exactly one number) or an interval.
- Handle edge cases when the nums array is empty.

Space & Time

Time Complexity: $O(n)$, where n is the length of the nums array, since we iterate through the array once.

Space Complexity: $O(1)$ additional space (ignoring the output list), as we only use a few extra variables.

Solution

The solution leverages a single pass through the input array and calculates the missing ranges by comparing the expected number with the current number in nums. First, initialize a variable "prev" to one less than the lower bound so that missing numbers from the very start of the range can be handled uniformly. For each number in the array, if there is a gap between prev and the current number (i.e., current number is at least 2 more than prev), then add the missing range (prev+1 to current number-1) to the output list. Update "prev" to the current number and finally handle any gap between the last number and the upper bound. The primary data structures used are the list for the output; the approach is iterative.

#346 Moving Average from Data Stream [Easy]

Key Insights

- Use a queue (or circular buffer) to keep track of the current window elements.
- Maintain a running sum to quickly update the window's total when a new element comes in.
- When the window is full, subtract the value of the element that falls out as a new one is added.
- Each call to next() is executed in constant time, $O(1)$.

Space & Time

Time Complexity: $O(1)$ per call to next()

Space Complexity: $O(\text{window size})$

Solution

The solution leverages a queue data structure to store the elements of the sliding window. A running sum variable is maintained for efficient calculation of the moving average. When a new integer is added:

- If the size of the queue is equal to the maximum window size, remove the oldest element and subtract its value from the running sum.
- Add the new element to both the queue and the running sum.
- Compute and return the moving average as the running sum divided by the number of elements in the queue. This approach ensures that each update is done in constant time without having to sum all elements in the window repeatedly.

#760 Find Anagram Mappings [Easy]

Key Insights

- Since nums2 is an anagram of nums1, every element in nums1 has a corresponding position in nums2.
- A dictionary (or hash table) can be used to map each number in nums2 to its indices.
- When iterating through nums1, we can assign the next available index from the dictionary for that number.

Space & Time

Time Complexity: $O(n)$ where n is the number of elements in the arrays (single pass to build the dictionary and another pass to form the mapping).

Space Complexity: $O(n)$ for storing the dictionary that holds indices of elements in nums2.

Solution

The approach consists of two primary steps:

- Build a dictionary to record all indices where each number appears in nums2. This dictionary maps a number to a list of indices.
- Iterate over nums1 and for each element, remove (or pop) one index from the corresponding list in the dictionary, and add that index to the final mapping array. This guarantees that each number from nums1 is correctly mapped to one of its positions in nums2 while efficiently handling duplicates.

#1426 Counting Elements [Easy]

Key Insights

- Use a hash table or set to store unique elements from arr for constant time lookups.
- Iterate through each element in arr and check if $x + 1$ exists in the set.
- Count each valid occurrence, including duplicates.
- This approach efficiently handles the problem without needing nested loops.

Space & Time

Time Complexity: $O(n)$, where n is the number of elements in arr (set lookups are $O(1)$ on average).

Space Complexity: $O(n)$, due to the use of an auxiliary set to store unique elements.

Solution

The solution leverages a set to achieve constant time membership checks. First, we convert arr to a set of unique numbers. Then, iterate through arr, and for each element, check if (element + 1) exists in the set. If it does, increment the count. This approach correctly handles duplicates by counting each occurrence during iteration.

#1534 Count Good Triplets [Easy]

Key Insights

- Brute force approach using three nested loops is acceptable since the maximum array length is 100.
- Check all possible triplets and count only those meeting the specified conditions.
- Absolute difference comparisons are the key condition validations.

Space & Time

Time Complexity: $O(n^3)$ where n is the length of the array.

Space Complexity: $O(1)$ extra space (ignoring input space).

Solution

We use a brute force algorithm with three nested loops, iterating over all combinations of triplets (i, j, k) ensuring $i < j < k$. For each triplet, we calculate the absolute differences:

– $|arr[i] - arr[j]| - |arr[j] - arr[k]| - |arr[i] - arr[k]|$ The triplet is counted as good if all absolute differences satisfy the conditions ($\leq a$, $\leq b$, and $\leq c$ respectively). This simple approach leverages the small input size, eliminating the need for more complex data structures or optimizations.

#57 Insert Interval [Medium]

Key Insights

- The intervals array is sorted by start times.
- Three main steps are used:
- Add intervals that come completely before the new interval.
- Merge overlapping intervals with the new interval.
- Append intervals that start after the new (merged) interval.
- Iterating through the list once allows an $O(n)$ solution.

Space & Time

Time Complexity: $O(n)$ since we scan the list once.

Space Complexity: $O(n)$ to store the resulting list of intervals.

Solution

Traverse the intervals list and perform the following:

– Append all intervals that end before the new interval starts. – For intervals that overlap with `newInterval`, update `newInterval` to merge them (using `min` for start and `max` for end). – Append the new merged interval. – Append all remaining intervals. This ensures that all intervals remain non-overlapping and sorted with a single pass.

#238 Product of Array Except Self [Medium]

Key Insights

- The product for each index can be computed by multiplying the product of all numbers to the left and the product of all numbers to the right of that index.
- Division is not allowed, so we must compute the cumulative products explicitly.
- Create two passes: one forward pass for prefix products and one backward pass for suffix products.
- Use the output array to store the cumulative product values, achieving $O(1)$ extra space by not using additional arrays.

Space & Time

Time Complexity: $O(n)$ because we iterate through the array twice.

Space Complexity: $O(1)$ extra space (excluding the output array).

Solution

The approach uses two passes over the input array:

– Initialize the answer array and fill it with prefix products. For each index `i`, `answer[i]` contains the product of all elements before `i`. – Traverse the array from the end using a running suffix product. Update the answer array by multiplying the current suffix product with the prefix product already stored. This method leverages an output array to store intermediate results and uses a temporary variable for the suffix product, ensuring constant extra space.

#281 Zigzag Iterator [Medium]

Key Insights

- Use a FIFO (first-in-first-out) structure to maintain the order of vectors which still have remaining elements.
- For each call to `next()`, select the next element from the current vector and then move that vector to the end of the queue if it still contains elements.
- The approach ensures proper zigzag (or cyclic) ordering among the vectors.
- When extending to `k` vectors, the same approach works: initialize the queue with each non-empty vector.

Space & Time

Time Complexity: $O(1)$ per `next()` call on average, with an overall $O(n)$ for n total elements.

Space Complexity: $O(k)$ for the queue structure (where k is the number of vectors), plus the storage for the input vectors.

Solution

We can solve the Zigzag Iterator problem by using a queue (or deque) to hold pairs of the vector's current index and the vector itself. For each call to `next()`, we remove the front element from the queue, return the current item from its associated vector, and if the vector has more elements, reinsert the pair (with an updated index) into the back of the queue. This cyclic process naturally interleaves the elements from the provided vectors.

#307 Range Sum Query – Mutable [Medium]

Key Insights

- To efficiently support both point updates and range sum queries, a specialized data structure like a Binary Indexed Tree (Fenwick Tree) or a Segment Tree is ideal.
- Both data structures provide update and sum query operations in $O(\log n)$ time.
- The challenge is to maintain a mutable array while enabling fast sum computation over any specified range.

Space & Time

Time Complexity: $O(\log n)$ for both update and `sumRange` operations

Space Complexity: $O(n)$ to store the additional tree structure

Solution

We can use a Binary Indexed Tree (Fenwick Tree) to solve this problem. The Fenwick Tree allows for efficient prefix sum calculations and point updates, both in $O(\log n)$ time. The approach involves:

- Building the Fenwick Tree using the initial array.
- On an update, computing the difference between the new value and the current value, then propagating the change appropriately in the tree.
- For the sum range query, computing the prefix sum up to right and subtracting the prefix sum up to left-1.

#454 4Sum II [Medium]

Key Insights

- Use a hash table to store the frequency of all possible sums from `nums1` and `nums2`.
- For each pair from `nums3` and `nums4`, compute the complement (negative sum) and look it up in the hash table.
- This reduces the time complexity from $O(n^4)$ to $O(n^2)$.

Space & Time

Time Complexity: $O(n^2)$ where n is the length of each array.

Space Complexity: $O(n^2)$ due to the storage of pair sums in the hash table.

Solution

The solution employs a hash table to precompute and store the frequency of sums of all pairs from the first two arrays. Then, by iterating over all pairs from the third and fourth arrays, we calculate the required complement that would result in a total sum of zero. This complement is checked in the hash table, and the frequency (number of valid pairs) is added to the result. This method efficiently finds the number of valid quadruplets without resorting to a brute-force $O(n^4)$ approach.

#525 Contiguous Array [Medium]

Key Insights

- Convert 0s to -1 so that a balanced subarray (equal number of 0s and 1s) sums to zero.
- Use a prefix sum to track the cumulative sum as you iterate through the array.
- Use a hash table (or dictionary) to store the first occurrence of each prefix sum.
- When the same prefix sum is encountered again, it indicates that the subarray between these indices is balanced.

Space & Time

Time Complexity: $O(n)$ – We iterate through the array once.

Space Complexity: $O(n)$ – In the worst case, we store an entry for each prefix sum.

Solution

We use a technique where we convert each 0 in the array to -1. Then, we compute a running prefix sum as we iterate through the array. A prefix sum of 0 at any point indicates that the subarray from the beginning to the current index is balanced. For each prefix sum, if we have seen it before, the subarray between the previous index (where the prefix sum was first seen) and the current index sums to 0. We update the maximum length accordingly. We use a hash table to store the first index where each prefix sum occurs.

#560 Subarray Sum Equals K [Medium]

Key Insights

- Utilize the prefix sum technique to simplify sum calculation for subarrays.
- Use a hash table (or dictionary/map) to store the frequency of prefix sums encountered.
- For each element, check if (current prefix sum – k) exists in the hash table; if it does, it indicates a valid subarray.
- Initialize the hash table with {0: 1} to manage cases where a subarray's sum is exactly k.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(n)$

Solution

We solve the problem by maintaining a running sum (prefix sum) and using a hash table to record the number of times each sum has occurred. As we iterate through the array, we update the running sum. For each new sum, we check if (current sum – k) exists in our hash table. If it does, the value associated with (current sum – k) gives the number of subarrays ending at the current index that sum to k. This method efficiently computes the result in a single pass through the array.

#1010 Pairs of Songs With Total Durations Divisible by 60 [Medium]

Key Insights

- Each song duration's effect is determined by its remainder when divided by 60.
- For any given module value r (where $0 \leq r < 60$), the complementary module needed to complete 60 is $(60 - r) \% 60$.
- Special handling is needed when r is 0 (or 30, since $30 + 30 = 60$) to avoid double-counting.
- A frequency counter for remainders can be efficiently used to count valid pairs in one pass through the list.

Space & Time

Time Complexity: $O(n)$, where n is the number of songs.

Space Complexity: $O(60) \rightarrow O(1)$, since we only need to keep track of 60 possible remainders.

Solution

We iterate over the list of song durations and calculate the remainder of each duration modulo 60. A frequency array (or hash table) is used to record how many times each remainder has been seen so far. For each song, we look up the frequency of its complementary remainder (i.e., $(60 - \text{current_remainder}) \% 60$) already encountered. This frequency indicates how many valid pairs can be formed with the current song. After counting pairs with the current song, we update the frequency of its remainder for future pairings.

#1272 Remove Interval [Medium]

Key Insights

- Iterate over each interval and check if it overlaps with the toBeRemoved interval.
- If the current interval is completely outside of toBeRemoved, add it to the result as is.
- For overlapping intervals, compute the non-overlapping portions:
- If the left side of the interval lies before toBeRemoved, include $[\text{start}, \min(\text{end}, \text{toBeRemoved.start})]$.

- If the right side of the interval lies after `toBeRemoved`, include `[max(start, toBeRemoved.end), end]`.

Space & Time

Time Complexity: $O(n)$, where n is the number of intervals.

Space Complexity: $O(n)$, for storing the resulting intervals.

Solution

The approach involves iterating through the list of sorted disjoint intervals and checking for overlap with the `toBeRemoved` interval. For each interval:

- If it is completely before or after the removal interval, add it directly to the result.
- If it overlaps with `toBeRemoved`, determine the remaining portion(s): The left side of the interval that does not intersect (if any). The right side of the interval that does not intersect (if any). Use simple conditional checks and list manipulation to form the final set of intervals.

#1429 First Unique Number [Medium]

Key Insights

- Use a queue to maintain the order of potential unique numbers.
- Use a hash table (or map) to count the occurrences of each number.
- When showing the first unique number, remove numbers from the front of the queue if their frequency is more than one.
- All operations (add and `showFirstUnique`) can be done in $O(1)$ amortized time.

Space & Time

Time Complexity: $O(1)$ amortized for each add and `showFirstUnique` call.

Space Complexity: $O(n)$, where n is the number of distinct integers encountered.

Solution

We design the `FirstUnique` class using two main data structures: a queue and a hash map (or dictionary). The queue preserves the order of insertion for unique candidates, while the hash map holds the frequency count for each integer.

When a new number is added:

- Increment its count in the hash map.
- If the count is one, append it to the queue.

To retrieve the first unique number:

- While the queue is not empty and the count for the element at the front is greater than one, remove it from the queue.
- Return the front element of the queue if it exists, otherwise return `-1`.

This approach ensures that we are always up-to-date with the current first unique number.

#3159 Find Occurrences of an Element in an Array [Medium]

Key Insights

- Scan the array once and record every index where `nums[i] == x``.
- Store those indices in order inside a `positions` array.
- For each query `k``, check whether the `k``-th occurrence exists.
- If it exists, return `positions[k - 1]``.
- Otherwise, return `-1``.
- This lets every query be answered in constant time after the preprocessing pass.

Space & Time

Time Complexity: $O(n + q)$, where n is the length of `nums`` and q is the number of queries.

Space Complexity: $O(m)$, where m is the number of occurrences of `x``.

Solution

We solve the problem by first precomputing all occurrences of `x``. As we iterate through `nums``, every time we see `x``, we append its index to an array called `positions``. Then, for each query value `k``, we check whether `k`` is

within the bounds of `positions`. If it is, the answer is `positions[k - 1]`; otherwise, the required occurrence does not exist, so the answer is `-1`. This avoids rescanning the array for every query.

#41 First Missing Positive [Hard]

Key Insights

- The missing positive number must be in the range $[1, n+1]$ where n is the length of the array.
- Use the array indices to place numbers in their correct positions (i.e., number i should be at index $i-1$) with in-place swapping.
- After rearrangement, scan the array: the first index where the number is not equal to $\text{index}+1$ indicates the missing positive integer.

Space & Time

Time Complexity: $O(n)$ as each number is swapped at most once.

Space Complexity: $O(1)$ since the rearrangement occurs in-place.

Solution

The approach involves reordering the array so that each positive integer in the range $[1, n]$ is placed at the index corresponding to its value minus one. This means for any valid number i , `nums[i-1]` should be i . We iterate through the array and perform in-place swaps to achieve this order. After this process, another pass through the array reveals the first position where the number does not match the expected value ($i+1$), which is the smallest missing positive. If every position is correct, then the missing value is $n+1$.

EASY

Merge Sorted Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Sorting](#)

Lists: Denny Zhang

Problem:

You are given two integer arrays `nums1` and `nums2`, sorted in non-decreasing order, and two integers `m` and `n`, representing the number of elements in `nums1` and `nums2` respectively.

Merge `nums1` and `nums2` into a single array sorted in non-decreasing order.

The final sorted array should not be returned by the function, but instead be stored inside the array `nums1`. To accommodate this, `nums1` has a length of `m + n`, where the first `m` elements denote the elements that should be merged, and the last `n` elements are set to 0 and should be ignored. `nums2` has a length of `n`.

Example 1:

Input: `nums1 = [1,2,3,0,0,0]`, `m = 3`, `nums2 = [2,5,6]`, `n = 3`

Output: `[1,2,2,3,5,6]`

Explanation: The arrays we are merging are `[1,2,3]` and `[2,5,6]`.

The result of the merge is `[1,2,2,3,5,6]` with the underlined elements coming from `nums1`.

Example 2:

Input: `nums1 = [1]`, `m = 1`, `nums2 = []`, `n = 0`

Output: `[1]`

Explanation: The arrays we are merging are `[1]` and `[]`.

The result of the merge is `[1]`.

Example 3:

Input: `nums1 = [0]`, `m = 0`, `nums2 = [1]`, `n = 1`

Output: `[1]`

Explanation: The arrays we are merging are `[]` and `[1]`.

The result of the merge is `[1]`.

Note that because `m = 0`, there are no elements in `nums1`. The 0 is only there to ensure the merge result can fit in `nums1`.

Constraints:

- `nums1.length == m + n`
- `nums2.length == n`
- `0 <= m, n <= 200`
- `1 <= m + n <= 200`
- `-109 <= nums1[i], nums2[j] <= 109`

Follow up: Can you come up with an algorithm that runs in $O(m + n)$ time?

[*] Two Pointers — Pattern Solution (stored optimal)

Python

```
def merge(nums1, m, nums2, n):
    # Initialize pointers for nums1, nums2 and the tail index
    p1 = m - 1
    p2 = n - 1
    tail = m + n - 1

    # Merge arrays from the end by choosing the larger element
    while p1 >= 0 and p2 >= 0:
        if nums1[p1] > nums2[p2]:
            nums1[tail] = nums1[p1]
            p1 -= 1 # Move pointer in nums1
        else:
            nums1[tail] = nums2[p2]
            p2 -= 1 # Move pointer in nums2
        tail -= 1 # Move tail pointer

    # Copy any remaining elements from nums2 into nums1
    while p2 >= 0:
        nums1[tail] = nums2[p2]
        p2 -= 1
        tail -= 1
```

C++

```

#include <vector>
using namespace std;

void merge(vector<int>& nums1, int m, vector<int>& nums2, int n) {
    // Initialize pointers for nums1, nums2 and the tail index of nums1
    int p1 = m - 1, p2 = n - 1, tail = m + n - 1;

    // Merge arrays starting from the end
    while (p1 >= 0 && p2 >= 0) {
        if (nums1[p1] > nums2[p2]) {
            nums1[tail] = nums1[p1];
            p1--; // Move pointer in nums1
        } else {
            nums1[tail] = nums2[p2];
            p2--; // Move pointer in nums2
        }
        tail--; // Move the tail pointer
    }

    // Copy any remaining elements from nums2 into nums1
    while (p2 >= 0) {
        nums1[tail] = nums2[p2];
        p2--;
        tail--;
    }
}

EASY

Valid Palindrome

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [String](#)

Lists: Grind 169

Problem:

A phrase is a palindrome if, after converting all uppercase letters into lowercase letters and removing all non-alphanumeric characters, it reads the same forward and backward. Alphanumeric characters include letters and numbers.

Given a string *s*, return true if it is a palindrome, or false otherwise.

Example 1:

Input: *s* = "A man, a plan, a canal: Panama"

Output: true

Explanation: "amanaplanacanalpanama" is a palindrome.

Example 2:

Input: *s* = "race a car"

Output: false

Explanation: "raceacar" is not a palindrome.

Example 3:

Input: s = " "

Output: true

Explanation: s is an empty string "" after removing non-alphanumeric characters. Since an empty string reads the same forward and backward, it is a palindrome.

Constraints:

- $1 \leq s.length \leq 2 * 10^5$
- s consists only of printable ASCII characters.

Python

Python

```
class Solution:
    def isPalindrome(self, s: str) -> bool:
        # Initialize two pointers at the beginning and end of the string
        left, right = 0, len(s) - 1
        while left < right:
            # Skip non-alphanumeric characters from the left
            while left < right and not s[left].isalnum():
                left += 1
            # Skip non-alphanumeric characters from the right
            while left < right and not s[right].isalnum():
                right -= 1
            # Compare the characters in lowercase
            if s[left].lower() != s[right].lower():
                return False
            left += 1
            right -= 1
        return True
```

Python

```

Move Zeroes

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#)

Lists: Grind 169

Problem:

Given an integer array `nums`, move all 0's to the end of it while maintaining the relative order of the non-zero elements.

Note that you must do this in-place without making a copy of the array.

Example 1:

Input: `nums = [0,1,0,3,12]`
Output: `[1,3,12,0,0]`

Example 2:

Input: `nums = [0]`
Output: `[0]`

Constraints:

- `1 <= nums.length <= 104`
- `-231 <= nums[i] <= 231 - 1`

Follow up: Could you minimize the total number of operations done?

Python

```
# Brute Force Approach
class Solution:
    def moveZeroes(self, nums):
        # Brute Force O(n^2) - nested loops instead of two pointers
        n = len(nums)
        for i in range(n):
            for j in range(i + 1, n):
                # check nums[i] and nums[j]
                pass
```

Python

Python

```
# Moves all zeros in the list 'nums' to the end in-place.
def moveZeroes(nums):
    # 'j' is the pointer where the next non-zero element should be placed.
    j = 0
    # Loop through all the elements with index 'i'
    for i in range(len(nums)):
        # Check if the current element is non-zero.
        if nums[i] != 0:
            # Swap only if i is not equal to j to avoid unnecessary operations.
            nums[j], nums[i] = nums[i], nums[j]
            # Increment j to move to the next insertion index.
            j += 1

# Example usage:
nums = [0, 1, 0, 3, 12]

EASY

Valid Word Abbreviation

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [String](#)

Lists: Premium 98

Problem:

A string can be abbreviated by replacing any number of non-adjacent, non-empty substrings with their lengths. The lengths should not have leading zeros.

For example, a string such as "substitution" could be abbreviated as (but not limited to):

- "s10n" ("s ubstitutio n")
- "sub4u4" ("sub stit u tion")
- "12" ("substitution")
- "su3i1u2on" ("su bst i t u ti on")
- "substitution" (no substrings replaced)

The following are not valid abbreviations:

- "s55n" ("s ubsti tutio n", the replaced substrings are adjacent)
- "s010n" (has leading zeros)
- "s0ubstitution" (replaces an empty substring)

Given a string word and an abbreviation abbr, return whether the string matches the given abbreviation.

A substring is a contiguous non-empty sequence of characters within a string.

Example 1:

Input: word = "internationalization", abbr = "i12iz4n"

Output: true

Explanation: The word "internationalization" can be abbreviated as "i12iz4n" ("i nternational iz atio n").

Example 2:

Input: word = "apple", abbr = "a2e"

Output: false

Explanation: The word "apple" cannot be abbreviated as "a2e".

Constraints:

- $1 \leq \text{word.length} \leq 20$
- word consists of only lowercase English letters.
- $1 \leq \text{abbr.length} \leq 10$
- abbr consists of lowercase English letters and digits.
- All the integers in abbr will fit in a 32-bit integer.

Python

Python

```
# Python solution for valid word abbreviation

def validWordAbbreviation(word: str, abbr: str) -> bool:
    word_index = 0 # pointer for the word
    abbr_index = 0 # pointer for the abbreviation

    while abbr_index < len(abbr):
        # if current abbrev char is a digit
        if abbr[abbr_index].isdigit():
            # leading zero check: if the digit is '0', it is invalid
            if abbr[abbr_index] == '0':
                return False
            # build the entire number
            num = 0
            while abbr_index < len(abbr) and abbr[abbr_index].isdigit():
                num = num * 10 + int(abbr[abbr_index])
                abbr_index += 1
            # skip num characters in word
            word_index += num
        else:
            # if letter doesn't match or word index is out of bounds, invalid
            if word_index >= len(word) or word[word_index] != abbr[abbr_index]:
                return False
            word_index += 1
            abbr_index += 1
```

```

    # Valid if and only if the entire word was covered

Python

```

# Python solution for valid word abbreviation

def validWordAbbreviation(word: str, abbr: str) -> bool:
    word_index = 0 # pointer for the word
    abbr_index = 0 # pointer for the abbreviation

    while abbr_index < len(abbr):
        # if current abbrev char is a digit
        if abbr[abbr_index].isdigit():
            # leading zero check: if the digit is '0', it is invalid
            if abbr[abbr_index] == '0':
                return False
            # build the entire number
            num = 0
            while abbr_index < len(abbr) and abbr[abbr_index].isdigit():
                num = num * 10 + int(abbr[abbr_index])
                abbr_index += 1
            # skip num characters in word
            word_index += num
        else:
            # if letter doesn't match or word index is out of bounds, invalid
            if word_index >= len(word) or word[word_index] != abbr[abbr_index]:
                return False
            word_index += 1
            abbr_index += 1

    # Valid if and only if the entire word was covered
    return word_index == len(word)

# Example usage:
#print(validWordAbbreviation("internationalization", "i12iz4n")) # Expected output: True
#print(validWordAbbreviation("apple", "a2e")) # Expected output: False

```

C++

```
// C++ solution for valid word abbreviation

#include <string>
using namespace std;

class Solution {
public:
    bool validWordAbbreviation(string word, string abbr) {
        int wordIndex = 0; // pointer for word
        int abbrIndex = 0; // pointer for abbreviation
        int wordLen = word.size();
        int abbrLen = abbr.size();

        while (abbrIndex < abbrLen) {
            if (isdigit(abbr[abbrIndex])) {
                // leading zero check
                if (abbr[abbrIndex] == '0') return false;
                int num = 0;
                // build the full number
                while (abbrIndex < abbrLen && isdigit(abbr[abbrIndex])) {
                    num = num * 10 + (abbr[abbrIndex] - '0');
                    abbrIndex++;
                }
                wordIndex += num; // skip num characters in word
            } else {
                // check for letter matching or if wordIndex out of bounds

EASY

Squares of a Sorted Array

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given an integer array `nums` sorted in non-decreasing order, return an array of the squares of each number sorted in non-decreasing order.

Example 1:

Input: `nums = [-4,-1,0,3,10]`

Output: `[0,1,9,16,100]`

Explanation: After squaring, the array becomes `[16,1,0,9,100]`.

After sorting, it becomes `[0,1,9,16,100]`.

Example 2:

Input: `nums = [-7,-3,2,3,11]`

Output: `[4,9,9,49,121]`

Constraints:

- `1 <= nums.length <= 104`
- `-104 <= nums[i] <= 104`
- `nums` is sorted in non-decreasing order.

Follow up: Squaring each element and sorting the new array is very trivial, could you find an $O(n)$ solution using a different approach?

>> Brute Force [Two Pointers] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def sortedSquares(self, nums):
        # Brute Force  $O(n^2)$  - nested loops instead of two pointers
        n = len(nums)
        for i in range(n):
            for j in range(i + 1, n):
                # check nums[i] and nums[j]
            pass
```

Python

Python

```

# Function to return squares of a sorted array in non-decreasing order.
def sortedSquares(nums):
    # Initialize two pointers at the start and end of the array.
    left, right = 0, len(nums) - 1
    # Create a result array of the same length as nums.
    result = [0] * len(nums)
    # Index to insert the largest square at the current position.
    position = len(nums) - 1

    # Loop until the left and right pointers cross.
    while left <= right:
        # Compare absolute values at the left and right pointers.
        if abs(nums[left]) > abs(nums[right]):
            result[position] = nums[left] * nums[left]
            left += 1 # Move left pointer rightward.
        else:
            result[position] = nums[right] * nums[right]
            right -= 1 # Move right pointer leftward.
        position -= 1 # Move to the next insertion position.
    return result

# Example usage:
print(sortedSquares([-4, -1, 0, 3, 10])) # Output: [0, 1, 9, 16, 100]

```

Python

Container With Most Water

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Greedy](#)

Lists: Grind 169

Problem:

You are given an integer array `height` of length `n`. There are `n` vertical lines drawn such that the two endpoints of the `i`th line are $(i, 0)$ and $(i, \text{height}[i])$.

Find two lines that together with the `x`-axis form a container, such that the container contains the most water.

Return the maximum amount of water a container can store.

Notice that you may not slant the container.

Example 1:

Input: `height = [1,8,6,2,5,4,8,3,7]`

Output: 49

Explanation: The above vertical lines are represented by array `[1,8,6,2,5,4,8,3,7]`. In this case, the max area of water (blue section) the container can contain is 49.

Example 2:

Input: `height = [1,1]`

Output: 1

Constraints:

- `n == height.length`
- `2 <= n <= 105`
- `0 <= height[i] <= 104`

Lists: Grind 169

Problem:

Given an integer array `nums`, return all the triplets `[nums[i], nums[j], nums[k]]` such that `i != j`, `i != k`, and `j != k`, and `nums[i] + nums[j] + nums[k] == 0`.

Notice that the solution set must not contain duplicate triplets.

Example 1:

Input: `nums = [-1,0,1,2,-1,-4]`

Output: `[[-1,-1,2],[-1,0,1]]`

Explanation:

`nums[0] + nums[1] + nums[2] = (-1) + 0 + 1 = 0.`

`nums[1] + nums[2] + nums[4] = 0 + 1 + (-1) = 0.`

`nums[0] + nums[3] + nums[4] = (-1) + 2 + (-1) = 0.`

The distinct triplets are `[-1,0,1]` and `[-1,-1,2]`.

Notice that the order of the output and the order of the triplets does not matter.

Example 2:

Input: `nums = [0,1,1]`

Output: `[]`

Explanation: The only possible triplet does not sum up to 0.

Example 3:

Input: `nums = [0,0,0]`

Output: `[[0,0,0]]`

Explanation: The only possible triplet sums up to 0.

Constraints:

- `3 <= nums.length <= 3000`
- `-105 <= nums[i] <= 105`

MEDIUM

3Sum Closest

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)[Array](#) · [Two Pointers](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given an integer array `nums` of length `n` and an integer `target`, find three integers at distinct indices in `nums` such that the sum is closest to `target`.

Return the sum of the three integers.

You may assume that each input would have exactly one solution.

Example 1:

Input: `nums = [-1,2,1,-4]`, `target = 1`

Output: `2`

Explanation: The sum that is closest to the target is 2. ($-1 + 2 + 1 = 2$).

Example 2:

Input: `nums = [0,0,0]`, `target = 1`

Output: `0`

Explanation: The sum that is closest to the target is 0. ($0 + 0 + 0 = 0$).

Constraints:

- $3 \leq \text{nums.length} \leq 500$
- $-1000 \leq \text{nums}[i] \leq 1000$
- $-104 \leq \text{target} \leq 104$

Python

```

# Python solution for 3Sum Closest
def threeSumClosest(nums, target):
    # Sort the array to allow two pointer technique
    nums.sort()
    # Initialize best_sum with the sum of the first three elements
    best_sum = sum(nums[:3])

    # Iterate through each number as the fixed element
    for i in range(len(nums) - 2):
        left, right = i + 1, len(nums) - 1
        # Use two pointers to check pairs
        while left < right:
            current_sum = nums[i] + nums[left] + nums[right]
            # Update best_sum if current_sum is closer to target
            if abs(target - current_sum) < abs(target - best_sum):
                best_sum = current_sum
            # Move left pointer if current_sum is less than target to increase sum
            if current_sum < target:
                left += 1
            # Move right pointer if current_sum is greater than target to decrease sum
            elif current_sum > target:
                right -= 1
            else:
                # If the current_sum exactly equals target, return the target sum
                return current_sum

    # Return the closest sum found
    return best_sum

# Example usage:
# print(threeSumClosest([-1,2,1,-4], 1))

```

Next Permutation

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#)

Lists: Grind 169

Problem:

A permutation of an array of integers is an arrangement of its members into a sequence or linear order.

- For example, for arr = [1,2,3], the following are all the permutations of arr: [1,2,3], [1,3,2], [2, 1, 3], [2, 3, 1], [3,1,2], [3,2,1].

The next permutation of an array of integers is the next lexicographically greater permutation of its integer. More formally, if all the permutations of the array are sorted in one container according to their lexicographical order, then the next permutation of that array is the permutation that follows it in the sorted container. If such arrangement is not possible, the array must be rearranged as the lowest possible order (i.e., sorted in ascending order).

- For example, the next permutation of arr = [1,2,3] is [1,3,2].
- Similarly, the next permutation of arr = [2,3,1] is [3,1,2].

- While the next permutation of $arr = [3,2,1]$ is $[1,2,3]$ because $[3,2,1]$ does not have a lexicographical larger rearrangement.

Given an array of integers `nums`, find the next permutation of `nums`.

The replacement must be in place and use only constant extra memory.

Example 1:

Input: `nums = [1,2,3]`
Output: `[1,3,2]`

Example 2:

Input: `nums = [3,2,1]`
Output: `[1,2,3]`

Example 3:

Input: `nums = [1,1,5]`
Output: `[1,5,1]`

Constraints:

- $1 \leq \text{nums.length} \leq 100$
- $0 \leq \text{nums}[i] \leq 100$

Sort Colors

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Sorting](#)

Lists: Grind 169

Problem:

Given an array `nums` with `n` objects colored red, white, or blue, sort them in-place so that objects of the same color are adjacent, with the colors in the order red, white, and blue.

We will use the integers 0, 1, and 2 to represent the color red, white, and blue, respectively.

You must solve this problem without using the library's sort function.

Example 1:

Input: `nums = [2,0,2,1,1,0]`

Output: `[0,0,1,1,2,2]`

Example 2:

Input: `nums = [2,0,1]`

Output: `[0,1,2]`

Constraints:

- `n == nums.length`
- `1 <= n <= 300`
- `nums[i]` is either 0, 1, or 2.

Follow up: Could you come up with a one-pass algorithm using only constant extra space?

[*] Two Pointers — Pattern Solution (stored optimal)

Python

```

# Function to sort the colors using Dutch National Flag algorithm
def sortColors(nums):
    # Initialize pointers for the start, current, and end positions
    low, mid, high = 0, 0, len(nums) - 1

    # Process elements until mid pointer exceeds high pointer
    while mid <= high:
        # If the current element is 0 (red)
        if nums[mid] == 0:
            # Swap current element with the element at low pointer
            nums[low], nums[mid] = nums[mid], nums[low]
            # Increment both low and mid pointers
            low += 1
            mid += 1
        # If the current element is 1 (white)
        elif nums[mid] == 1:
            # Move mid pointer forward since it's already in the correct place
            mid += 1
        # If the current element is 2 (blue)
        else:
            # Swap current element with the element at high pointer
            nums[mid], nums[high] = nums[high], nums[mid]
            # Decrement high pointer
            high -= 1

# Example usage:
nums = [2,0,2,1,1,0]
sortColors(nums)
print(nums) # Output: [0,0,1,1,2,2]

```

C++

```

// Function to sort the colors using Dutch National Flag algorithm
#include <vector>
#include <iostream>
using namespace std;

void sortColors(vector<int>& nums) {
    // Initialize pointers for low, mid, and high
    int low = 0, mid = 0;
    int high = nums.size() - 1;

    // Iterate until mid pointer exceeds high pointer
    while (mid <= high) {
        if (nums[mid] == 0) {
            // Swap element at mid with element at low pointer
            swap(nums[low], nums[mid]);
            low++;
            mid++;
        } else if (nums[mid] == 1) {
            // Move mid pointer forward if element is 1
            mid++;
        } else { // nums[mid] == 2
            // Swap element at mid with element at high pointer
            swap(nums[mid], nums[high]);
            high--;
        }
    }
}

```

```

    }
}

// Example usage:
int main() {
    vector<int> nums = {2,0,2,1,1,0};
    sortColors(nums);
    // Output the sorted array
    for (int num : nums)
        cout << num << " ";
    // Expected Output: 0 0 1 1 2 2
    return 0;
}

```

MEDIUM

One Edit Distance

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [String](#)

Lists: Premium 98

Problem:

Given two strings *s* and *t*, return true if they are both one edit distance apart, otherwise return false.

A string *s* is said to be one distance apart from a string *t* if you can:

- Insert exactly one character into *s* to get *t*.
- Delete exactly one character from *s* to get *t*.
- Replace exactly one character of *s* with a different character to get *t*.

Example 1:

Input: *s* = "ab", *t* = "acb"

Output: true

Explanation: We can insert 'c' into *s* to get *t*.

Example 2:

Input: *s* = "", *t* = ""

Output: false

Explanation: We cannot get *t* from *s* by only one step.

Constraints:

- $0 \leq s.length, t.length \leq 104$
- *s* and *t* consist of lowercase letters, uppercase letters, and digits.

Python

[Python](#)

```

# Function to check if two strings are one edit distance apart
def isOneEditDistance(s: str, t: str) -> bool:
    # Get lengths of both strings
    m, n = len(s), len(t)

    # The difference in length must not be greater than 1
    if abs(m - n) > 1:
        return False

    # Ensure s is the shorter string, or they are equal in length
    if m > n:
        return isOneEditDistance(t, s)

    # Initialize variables; found difference flag and indices for both strings
    found_difference = False
    i = j = 0

    while i < m and j < n:
        if s[i] != t[j]:
            # If a difference has already been found, return False
            if found_difference:
                return False
            found_difference = True
            # If lengths are equal, move both pointers
            if m == n:
                i += 1
            else:
                # If characters are the same, move the pointer in the shorter string
                i += 1
            # Always move pointer for longer string
            j += 1

    # If no difference was found during iteration, then one extra character at the end is the edit
    return found_difference or (j - i == 1)

# Example usage:
#print(isOneEditDistance("ab", "acb")) # Output: True

[*] Two Pointers — Pattern Solution (stored optimal)

Python

```

# Function to check if two strings are one edit distance apart
def isOneEditDistance(s: str, t: str) -> bool:
    # Get lengths of both strings
    m, n = len(s), len(t)

    # The difference in length must not be greater than 1
    if abs(m - n) > 1:
        return False

    # Ensure s is the shorter string, or they are equal in length
    if m > n:
        return isOneEditDistance(t, s)

    # Initialize variables; found difference flag and indices for both strings
    found_difference = False
    i = j = 0

    while i < m and j < n:
        if s[i] != t[j]:
            # If a difference has already been found, return False
            if found_difference:
                return False
            found_difference = True
            # If lengths are equal, move both pointers
            if m == n:
                i += 1
            else:
                # If characters are the same, move the pointer in the shorter string
                i += 1
            # Always move pointer for longer string
            j += 1

    # If no difference was found during iteration, then one extra character at the end is the edit
    return found_difference or (j - i == 1)

# Example usage:
#print(isOneEditDistance("ab", "acb")) # Output: True

```

C++

```

// Function to check if two strings are one edit distance apart
#include <string>
#include <cmath>
using namespace std;

class Solution {
public:
    bool isOneEditDistance(string s, string t) {
        int m = s.size(), n = t.size();

        // Difference in length should not exceed 1
        if (abs(m - n) > 1) return false;

        // Ensure s is the shorter string or equal in length
        if (m > n) return isOneEditDistance(t, s);

        bool foundDifference = false;
        int i = 0, j = 0;

        while (i < m && j < n) {
            if (s[i] != t[j]) {
                // If difference has been found already, return false
                if (foundDifference) return false;
                foundDifference = true;

                // For same length, increment i
                if (m == n) {
                    i++;
                }
            } else {
                // If characters match, always move i pointer
                i++;
            }
            // Move pointer j for the longer string
            j++;
        }

        // If no difference was found, check if extra missing character at the end qualifies
        return foundDifference || (j - i == 1);
    }
};

// Example usage:
// int main() {
//     Solution sol;
//     bool result = sol.isOneEditDistance("ab", "acb"); // Should return true
//     return 0;
// }

Two Sum II – Input Array Is Sorted

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Binary Search](#)

Lists: Denny Zhang

Problem:

Given a 1-indexed array of integers `numbers` that is already sorted in non-decreasing order, find two numbers such that they add up to a specific target number. Let these two numbers be `numbers[index1]` and `numbers[index2]` where $1 \leq \text{index1} < \text{index2} \leq \text{numbers.length}$.

Return the indices of the two numbers `index1` and `index2`, each incremented by one, as an integer array `[index1, index2]` of length 2.

The tests are generated such that there is exactly one solution. You may not use the same element twice.

Your solution must use only constant extra space.

Example 1:

Input: `numbers = [2,7,11,15]`, `target = 9`

Output: `[1,2]`

Explanation: The sum of 2 and 7 is 9. Therefore, `index1 = 1`, `index2 = 2`. We return `[1, 2]`.

Example 2:

Input: `numbers = [2,3,4]`, `target = 6`

Output: `[1,3]`

Explanation: The sum of 2 and 4 is 6. Therefore `index1 = 1`, `index2 = 3`. We return `[1, 3]`.

Example 3:

Input: `numbers = [-1,0]`, `target = -1`

Output: `[1,2]`

Explanation: The sum of `-1` and `0` is `-1`. Therefore `index1 = 1`, `index2 = 2`. We return `[1, 2]`.

Constraints:

- $2 \leq \text{numbers.length} \leq 3 \cdot 10^4$
- $-1000 \leq \text{numbers}[i] \leq 1000$
- `numbers` is sorted in non-decreasing order.
- $-1000 \leq \text{target} \leq 1000$
- The tests are generated such that there is exactly one solution.

Reverse Words in a String II

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [String](#)

Lists: Premium 98

Problem:

Given a character array *s*, reverse the order of the words.

A word is defined as a sequence of non-space characters. The words in *s* will be separated by a single space.

Your code must solve the problem in-place, i.e. without allocating extra space.

Example 1:

Input: *s* = ["t","h","e"," ","s","k","y"," ","i","s"," ","b","l","u","e"]

Output: ["b","l","u","e"," ","i","s"," ","s","k","y"," ","t","h","e"]

Example 2:

Input: *s* = ["a"]

Output: ["a"]

Constraints:

- $1 \leq s.length \leq 105$
- *s*[*i*] is an English letter (uppercase or lowercase), digit, or space ' '.
- There is at least one word in *s*.
- *s* does not contain leading or trailing spaces.
- All the words in *s* are guaranteed to be separated by a single space.

MEDIUM

Rotate Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Math](#) · [Two Pointers](#)

Lists: Grind 169

Problem:

Given an integer array `nums`, rotate the array to the right by `k` steps, where `k` is non-negative.

Example 1:

Input: `nums = [1,2,3,4,5,6,7]`, `k = 3`

Output: `[5,6,7,1,2,3,4]`

Explanation:

rotate 1 steps to the right: `[7,1,2,3,4,5,6]`

rotate 2 steps to the right: `[6,7,1,2,3,4,5]`

rotate 3 steps to the right: `[5,6,7,1,2,3,4]`

Example 2:

Input: `nums = [-1,-100,3,99]`, `k = 2`

Output: `[3,99,-1,-100]`

Explanation:

rotate 1 steps to the right: `[99,-1,-100,3]`

rotate 2 steps to the right: `[3,99,-1,-100]`

Constraints:

- `1 <= nums.length <= 105`
- `-231 <= nums[i] <= 231 - 1`
- `0 <= k <= 105`

Follow up:

- Try to come up with as many solutions as you can. There are at least three different ways to solve this problem.

- Could you do it in-place with $O(1)$ extra space?

K-diff Pairs in an Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Two Pointers](#) · [Binary Search](#) · [Sorting](#)

Lists: [CodeSignal](#)

Problem:

Given an array of integers `nums` and an integer `k`, return the number of unique `k`-diff pairs in the array.

A `k`-diff pair is an integer pair $(\text{nums}[i], \text{nums}[j])$, where the following are true:

- $0 \leq i, j < \text{nums.length}$
- $i \neq j$
- $|\text{nums}[i] - \text{nums}[j]| == k$

Notice that $|\text{val}|$ denotes the absolute value of `val`.

Example 1:

Input: `nums = [3,1,4,1,5]`, `k = 2`

Output: 2

Explanation: There are two 2-diff pairs in the array, (1, 3) and (3, 5).

Although we have two 1s in the input, we should only return the number of unique pairs.

Example 2:

Input: nums = [1,2,3,4,5], k = 1

Output: 4

Explanation: There are four 1-diff pairs in the array, (1, 2), (2, 3), (3, 4) and (4, 5).

Example 3:

Input: nums = [1,3,1,5,4], k = 0

Output: 1

Explanation: There is one 0-diff pair in the array, (1, 1).

Constraints:

- $1 \leq \text{nums.length} \leq 104$
- $-107 \leq \text{nums}[i] \leq 107$
- $0 \leq k \leq 107$

Lists: [CodeSignal](#)

Problem:

Given an integer array `arr`, and an integer `target`, return the number of tuples `i, j, k` such that $i < j < k$ and $arr[i] + arr[j] + arr[k] == target$.

As the answer can be very large, return it modulo $10^9 + 7$.

Example 1:

Input: `arr = [1,1,2,2,3,3,4,4,5,5]`, `target = 8`
 Output: 20
 Explanation:
 Enumerating by the values (`arr[i]`, `arr[j]`, `arr[k]`):
 (1, 2, 5) occurs 8 times;
 (1, 3, 4) occurs 8 times;
 (2, 2, 4) occurs 2 times;
 (2, 3, 3) occurs 2 times.

Example 2:

Input: `arr = [1,1,2,2,2,2]`, `target = 5`
 Output: 12
 Explanation:
`arr[i] = 1`, `arr[j] = arr[k] = 2` occurs 12 times:
 We choose one 1 from `[1,1]` in 2 ways,
 and two 2s from `[2,2,2,2]` in 6 ways.

Example 3:

Input: `arr = [2,1,3]`, `target = 6`
 Output: 1
 Explanation: (1, 2, 3) occurred one time in the array so we return 1.

Constraints:

- $3 \leq arr.length \leq 3000$

- $0 \leq \text{arr}[i] \leq 100$
- $0 \leq \text{target} \leq 300$

Interval List Intersections

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#)

Lists: Denny Zhang

Problem:

You are given two lists of closed intervals, `firstList` and `secondList`, where `firstList[i] = [starti, endi]` and `secondList[j] = [startj, endj]`. Each list of intervals is pairwise disjoint and in sorted order.

Return the intersection of these two interval lists.

A closed interval $[a, b]$ (with $a \leq b$) denotes the set of real numbers x with $a \leq x \leq b$.

The intersection of two closed intervals is a set of real numbers that are either empty or represented as a closed interval. For example, the intersection of $[1, 3]$ and $[2, 4]$ is $[2, 3]$.

Example 1:

Input: `firstList = [[0,2],[5,10],[13,23],[24,25]]`, `secondList = [[1,5],[8,12],[15,24],[25,26]]`

Output: `[[1,2],[5,5],[8,10],[15,23],[24,24],[25,25]]`

Example 2:

Input: `firstList = [[1,3],[5,9]]`, `secondList = []`

Output: `[]`

Constraints:

- $0 \leq \text{firstList.length}, \text{secondList.length} \leq 1000$
- $\text{firstList.length} + \text{secondList.length} \geq 1$
- $0 \leq \text{start}_i < \text{end}_i \leq 109$
- $\text{end}_i < \text{start}_{i+1}$
- $0 \leq \text{start}_j < \text{end}_j \leq 109$
- $\text{end}_j < \text{start}_{j+1}$

Shortest Way to Form String

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [String](#) · [Binary Search](#)

Lists: Premium 98

Problem:

A subsequence of a string is a new string that is formed from the original string by deleting some (can be none) of the characters without disturbing the relative positions of the remaining characters. (i.e., "ace" is a subsequence of "abcde" while "aec" is not).

Given two strings source and target, return the minimum number of subsequences of source such that their concatenation equals target. If the task is impossible, return -1.

Example 1:

Input: source = "abc", target = "abcbc"

Output: 2

Explanation: The target "abcbc" can be formed by "abc" and "bc", which are subsequences of source "abc".

Example 2:

Input: source = "abc", target = "acdbc"

Output: -1

Explanation: The target string cannot be constructed from the subsequences of source string due to the character "d" in target string.

Example 3:

Input: source = "xyz", target = "xzyxz"

Output: 3

Explanation: The target string can be constructed as follows "xz" + "y" + "xz".

Constraints:

- $1 \leq \text{source.length}, \text{target.length} \leq 1000$
- source and target consist of lowercase English letters.

Count the Number of Fair Pairs

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Binary Search](#) · [Sorting](#)

Lists: [CodeSignal](#)

Problem:

Given a 0-indexed integer array `nums` of size `n` and two integers `lower` and `upper`, return the number of fair pairs.

A pair (i, j) is fair if:

- $0 \leq i < j < n$, and
- $\text{lower} \leq \text{nums}[i] + \text{nums}[j] \leq \text{upper}$

Example 1:

Input: `nums = [0,1,7,4,4,5]`, `lower = 3`, `upper = 6`

Output: 6

Explanation: There are 6 fair pairs: $(0,3)$, $(0,4)$, $(0,5)$, $(1,3)$, $(1,4)$, and $(1,5)$.

Example 2:

Input: `nums = [1,7,9,2,5]`, `lower = 11`, `upper = 11`

Output: 1

Explanation: There is a single fair pair: $(2,3)$.

Constraints:

- $1 \leq \text{nums.length} \leq 105$
- $\text{nums.length} == n$
- $-109 \leq \text{nums}[i] \leq 109$
- $-109 \leq \text{lower} \leq \text{upper} \leq 109$

            const mid = (l + r) >> 1;
            if (nums[mid] >= x) {
                r = mid;
            } else {
                l = mid + 1;
            }
        }
        return l;
    };

    nums.sort((a, b) => a - b);
    let ans = 0;
    for (let i = 0; i < nums.length; ++i) {
        const j = search(lower - nums[i], i + 1);
        const k = search(upper - nums[i] + 1, i + 1);
        ans += k - j;
    }
    return ans;
}
```

Go

Go

```
func countFairPairs(nums []int, lower int, upper int) (ans int64) {
    sort.Ints(nums)
    for i, x := range nums {
        j := sort.Search(len(nums), func(h int) bool { return h > i && nums[h] >= lower-x })
        k := sort.Search(len(nums), func(h int) bool { return h > i && nums[h] >= upper-x+1 })
        ans += int64(k - j)
    }
    return
}
```

Go

```
func countFairPairs(nums []int, lower int, upper int) (ans int64) {
    sort.Ints(nums)
    for i, x := range nums {
        j := sort.Search(len(nums), func(h int) bool { return h > i && nums[h] >= lower-x })
        k := sort.Search(len(nums), func(h int) bool { return h > i && nums[h] >= upper-x+1 })
        ans += int64(k - j)
    }
    return
}
```

[*] Two Pointers — Pattern Solution (stored optimal)

Python

```
import bisect

def countFairPairs(nums, lower, upper):
    # Sort the array to allow binary search
    nums.sort()
    fair_pairs = 0
    n = len(nums)

    for i in range(n):
        # Find lower bound index for the required complement so that nums[i] + nums[j] >= lower
        left = bisect.bisect_left(nums, lower - nums[i], i + 1, n)
        # Find upper bound index for the required complement so that nums[i] + nums[j] <= upper
        right = bisect.bisect_right(nums, upper - nums[i], i + 1, n)
        fair_pairs += (right - left)

    return fair_pairs

# Example usage:
print(countFairPairs([0,1,7,4,4,5], 3, 6)) # Expected output: 6
```

C++

```

#include <iostream>
#include <vector>
#include <algorithm> // For sort, lower_bound, and upper_bound

using namespace std;

long long countFairPairs(vector<int>& nums, int lower, int upper) {
    // Sort the array to allow binary search.
    sort(nums.begin(), nums.end());
    long long fairPairs = 0;
    int n = nums.size();

    // Iterate over each element.
    for (int i = 0; i < n; i++) {
        // Find the lower bound index for the required complement:
        // nums[i] + nums[j] >= lower => nums[j] >= lower - nums[i]
        auto leftIt = lower_bound(nums.begin() + i + 1, nums.end(), lower - nums[i]);

        // Find the upper bound index:
        // nums[i] + nums[j] <= upper => nums[j] <= upper - nums[i]
        auto rightIt = upper_bound(nums.begin() + i + 1, nums.end(), upper - nums[i]);

        // Add the count of valid pairs for index i.
        fairPairs += (rightIt - leftIt);
    }

    return fairPairs;
}

int main() {
    vector<int> nums = {0,1,7,4,4,5};
    int lower = 3, upper = 6;
    cout << countFairPairs(nums, lower, upper) << endl; // Expected output: 6
    return 0;
}

```

Quick Review — Two Pointers 19 questions · insights · complexity · solution

#88 Merge Sorted Array [Easy]

Key Insights

- Both arrays are already sorted in non-decreasing order.
- The merge should be done in-place into nums1.
- Start merging from the end to avoid overwriting elements in nums1.
- Use two pointers, one for nums1 and one for nums2, and a tail pointer for placement.

Space & Time

Time Complexity: $O(m + n)$

Space Complexity: $O(1)$

Solution

We use a two-pointer approach starting from the end of both arrays. Initialize three pointers:

– p1 pointing to the last valid element in nums1. – p2 pointing to the last element in nums2. – tail pointing to the last index of nums1.

While both pointers are valid, compare the elements pointed by p1 and p2, placing the larger element at the tail position. Decrement the corresponding pointer and the tail pointer. Finally, if any elements remain in nums2 (i.e., $p2 \geq 0$), copy them over into nums1. This solution leverages the extra space at the end of nums1 and ensures the merge is done in-place in linear time.

#125 Valid Palindrome [Easy]

Key Insights

- Use two pointers (one starting at the beginning and one at the end) to compare characters.
- Skip characters that are not alphanumeric.
- Compare characters in a case-insensitive manner.
- Continue until the pointers meet or cross.

Space & Time

Time Complexity: $O(n)$, where n is the length of the string, as each character is processed at most once.

Space Complexity: $O(1)$, using only a few extra variables for pointers and temporary comparisons.

Solution

The solution employs a two-pointer approach:

– Initialize two pointers: one at the start (left) and one at the end (right) of the string. – Skip any non-alphanumeric characters using these pointers. – Convert the remaining characters at each pointer to lowercase and compare them. – If any mismatch is found, return false; otherwise, continue until the pointers cross. – Return true if all corresponding characters match. This method efficiently checks for a palindrome without needing additional space for a filtered string.

#283 Move Zeroes [Easy]

Key Insights

- Use a two-pointer technique: one pointer to iterate through the array and another pointer to track the position for the next non-zero element.
- For each non-zero element encountered, swap it with the element at the tracking pointer.
- This strategy minimizes operations by ensuring each non-zero element is moved at most once.
- After repositioning all non-zero elements, zeros will naturally occupy the remaining positions.
- The in-place requirement ensures space complexity remains $O(1)$.

Space & Time

Time Complexity: $O(n)$, where n is the number of elements in the array, since only one pass (or at most two simple passes) is required.

Space Complexity: $O(1)$ extra space, as the reordering is accomplished in-place.

Solution

The solution leverages a two-pointer approach. The left pointer (j) keeps track of the index where the next non-zero element should be placed, while the right pointer (i) iterates through the array. Whenever a non-zero element is encountered, it is swapped with the element at index j , and j is then incremented. This effectively gathers all non-zero elements at the beginning while moving zeros to the end. A key optimization is to perform the swap only when necessary (i.e., when i and j are not the same) to reduce the number of write operations.

#408 Valid Word Abbreviation [Easy]

Key Insights

- Use two pointers: one for looping through the word and one for the abbreviation.
- When encountering a digit in abbr, accumulate the number and skip that many characters in the word.
- Check for invalid cases such as numbers with leading zeros or consecutive digit segments that might imply adjacent skipped substrings.
- Compare letters directly when they are not digits.

Space & Time

Time Complexity: $O(n + m)$ where n is the length of the word and m is the length of the abbreviation.

Space Complexity: $O(1)$ (constant extra space)

Solution

The approach uses two pointers to iterate over the word and abbreviation. For each character in the abbreviation:

- If it is a letter, compare it with the current character in the word.
- If it is a digit, first ensure that it does not start with '0'. Then, convert the sequence of digits into a number which represents how many characters in the word to skip. After processing, both pointers should have reached the end of their respective strings for the abbreviation to be valid. This approach is efficient due to its linear pass with constant extra space.

#977 Squares of a Sorted Array [Easy]

Key Insights

- Squaring numbers can disrupt the original order since negative numbers become positive.
- A two-pointer approach can efficiently retrieve the largest square from either end of the array.
- By comparing the absolute values at the two pointers, the largest square is inserted from the back of the result array.
- This method achieves an $O(n)$ time complexity without needing to sort the squared values afterward.

Space & Time

Time Complexity: $O(n)$ – We traverse the array only once.

Space Complexity: $O(n)$ – We use an extra array to store the output.

Solution

We use a two-pointer technique to traverse the array from both ends. Initialize pointers (left and right) at the beginning and end of the array, respectively, and an index pointer starting at the end of a new results array. At each step, compare the absolute values of the elements at the left and right pointers. The larger absolute value, when squared, is placed in the result array at the current index, and the corresponding pointer is adjusted. This continues until the left pointer exceeds the right pointer. Filling the result array from the back ensures that the array remains sorted in non-decreasing order.

#11 Container With Most Water [Medium]

Key Insights

- The container's area is determined by the distance between two lines multiplied by the shorter line's height.
- A brute-force approach checking all possible pairs would result in $O(n^2)$ time complexity, which is inefficient for large inputs.
- A two-pointer approach allows us to solve the problem in $O(n)$ time by initializing pointers at both ends and gradually moving them inward.
- By always moving the pointer corresponding to the shorter line, we are more likely to find a taller line that could potentially form a container with a larger capacity.

Space & Time

Time Complexity: $O(n)$ – The algorithm makes a single pass through the array with two pointers.

Space Complexity: $O(1)$ – Only a few extra variables are used, regardless of the input size.

Solution

The optimal approach uses a two-pointer strategy:

- Start with two pointers at each end of the array.
- Calculate the area formed between the two lines at these pointers.
- Update the maximum area if the calculated value is larger.
- Move the pointer pointing to the shorter line inward, as this is the only possible way to potentially increase the height of the shorter line and thus the area.
- Continue until the two pointers meet.

This method effectively reduces the number of comparisons and ensures that every possible pair that can yield a larger area is considered.

#15 3Sum [Medium]

Key Insights

- Sort the array to efficiently skip duplicates and facilitate the two pointers approach.
- Use a fixed pointer for the first element, and then use two additional pointers (left and right) to find pairs that sum to the negation of the fixed element.
- Skip duplicate elements to ensure unique triplets.

Space & Time

Time Complexity: $O(n^2)$ where n is the number of elements in the array.

Space Complexity: $O(1)$ extra space (ignoring the space required for the output).

Solution

We first sort the array to bring duplicates together and allow the two-pointer technique to work efficiently. Then, iterate over the array and for each element, use two pointers (one at the beginning right after the current element and one at the end of the array) to find a pair that sums with the current element to zero. Skip duplicates for the current element and within the inner loop to avoid duplicate triplets. This ensures that each valid triplet is unique and the overall runtime remains efficient.

#16 3Sum Closest [Medium]

Key Insights

- Sort the array to make it easier to use the two pointers technique.
- Fix one element and then use two pointers (left and right) to find the best pair that, along with the fixed element, produces a sum closest to the target.
- Update the best sum whenever a closer sum is found.
- The sorted order helps eliminate unnecessary iterations and allows efficient movement of pointers.

Space & Time

Time Complexity: $O(n^2)$

Space Complexity: $O(\log n)$ to $O(n)$ depending on the sorting algorithm used (typically in-place sort, so extra space might be minimal)

Solution

The solution starts by sorting the array. For each index in the array (considered as the first element of the triple), we use two pointers: one starting just after the fixed element and the other at the end of the array. We calculate the sum of the fixed element and the two pointers. If this sum is closer to the target than the current best, we update our best sum. Depending on whether the current sum is less than or greater than the target, we adjust the left or right pointer to try and get closer to the target. This two-pointer method leverages the sorted order of the array for efficient summing.

#31 Next Permutation [Medium]

Key Insights

- The problem is solved by identifying the first pair from the right where the left element is less than the right element.
- Once this pivot is found, find the rightmost element that is greater than this pivot.
- Swap these two elements.
- Reverse the subarray that comes after the pivot to ensure the next permutation is the next lexicographically larger sequence.
- If no such pivot exists, the array is in descending order and should be reversed to get the smallest permutation.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

We start by scanning the array from the right to find the first index (i) such that $\text{nums}[i]$ is less than $\text{nums}[i+1]$. This index ' i ' represents the pivot point where the next permutation can be formed. If we find such an index, we then scan from the right again to locate the first number that is greater than $\text{nums}[i]$ (let this index be j), and swap these two numbers. Finally, we reverse the subarray starting from index $i+1$ to the end of the array, which gives us the next permutation in lexicographical order. This approach leverages in-place modifications using basic operations like swapping and reversing, thus meeting the constant space requirement.

#75 Sort Colors [Medium]

Key Insights

- Use the Dutch National Flag algorithm to partition the array into three sections.
- Maintain three pointers: one for the next position for 0 (low), one for the next position for 2 (high), and one to traverse the array (mid).
- Swap elements appropriately to ensure that all 0's are at the beginning, all 2's are at the end, and 1's remain in the middle.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

The solution uses a three-pointer approach (Dutch National Flag algorithm). Initialize three pointers: low, mid, and high. As you iterate through the array:

- If the element is 0, swap it with the element at the low pointer and increment both low and mid.
 - If the element is 1, simply move mid forward.
 - If the element is 2, swap it with the element at the high pointer and decrement high.
- This single pass method ensures that the array is sorted in-place with constant extra space. Key details include correctly handling swaps without losing any data and ensuring that the pointers are updated in the proper order.

#161 One Edit Distance [Medium]

Key Insights

- The difference in length between s and t must be at most 1.

- When lengths are equal, the only possibility is that exactly one character is different (replacement).
- When one string is longer by one character, the difference can be fixed by one insertion (or deletion in the other direction).
- Use two pointers to compare corresponding characters and carefully handle the first difference.

Space & Time

Time Complexity: $O(n)$, where n is the length of the shorter string, as we traverse both strings at most once.

Space Complexity: $O(1)$, using only constant extra space.

Solution

The solution uses a two-pointer approach. First, we check if the length difference is greater than 1, in which case they cannot be one edit apart. For the two primary cases:

- When strings are of equal length, iterate through both strings and count the number of differing characters. There should be exactly one difference.
- When lengths differ by one, use pointers for both strings. Upon encountering a difference, increment the pointer for the longer string only and ensure that no previous difference has been encountered. If a second discrepancy is found, return false. The key is to handle the edge case where the difference is at the end of the string.

#167 Two Sum II – Input Array Is Sorted [Medium]

Key Insights

- The array is sorted in non-decreasing order, which makes the two pointers technique very effective.
- Using two pointers (one at the start and one at the end) allows checking pairs and adjusting the pointers based on the sum.
- Since the problem guarantees exactly one solution and requires constant space, using two pointers satisfies both constraints.

Space & Time

Time Complexity: $O(n)$, where n is the number of elements in the array, because in the worst-case scenario each element is visited at most once.

Space Complexity: $O(1)$, as no additional data structure is used that scales with the input size.

Solution

We use the two pointers approach:

- Initialize two pointers, left at the beginning (index 0) and right at the end (last index) of the array.
 - While left is less than right, compute the sum of the elements at the two pointers.
 - If the sum equals the target, return the indices as $[\text{left}+1, \text{right}+1]$ (to adjust for the 1-indexed array).
 - If the sum is less than the target, move the left pointer to the right to increase the sum.
 - If the sum is greater than the target, move the right pointer to the left to decrease the sum.
- This approach leverages the sorted property and uses constant extra space.

#186 Reverse Words in a String II [Medium]

Key Insights

- Reverse the entire array first to obtain the reversed order of characters.
- Then, reverse each individual word to restore the correct letter order.
- Doing so leverages the two-pointer technique for in-place reversals.
- This method accomplishes the goal in $O(n)$ time while using $O(1)$ extra space.

Space & Time

Time Complexity: $O(n)$

Space Complexity: $O(1)$

Solution

The solution employs a two-step reversal process using the two-pointer technique. First, reverse the entire character array to reverse the overall order of characters. Although this reverses both the words and the letters in each word, it sets up the scenario where each word's letters are in reverse order. The next step is to iterate through

the array and locate each word (using the space character as a delimiter) and then reverse each word individually to correct its letter order. This process is done in-place without any additional data structures, conserving space.

#189 Rotate Array [Medium]

Key Insights

- The rotation amount k might be greater than the length of the array, so use $k \% n$ (where n is the array length) to compute the effective rotation.
- A smart in-place solution involves reversing sections of the array:
- Reverse the entire array.
- Reverse the first k elements.
- Reverse the remaining $n-k$ elements.
- Alternative approaches include using extra space or performing k single-step rotations (which is less optimal).

Space & Time

Time Complexity: $O(n)$ where n is the number of elements in the array.

Space Complexity: $O(1)$ if done in-place.

Solution

We solve the problem using the "reverse" technique to perform the rotation in-place. First, we adjust k by taking k modulo the length of the array to handle cases where k exceeds the array length. Then, we reverse the entire array. Next, we reverse the first k elements to restore their correct order. Finally, we reverse the remaining $n-k$ elements. This sequence yields the array rotated to the right by k positions while strictly using $O(1)$ extra space.

#532 K-diff Pairs in an Array [Medium]

Key Insights

- For $k < 0$, the answer is always 0 because the absolute difference cannot be negative.
- When k is 0, you are looking for numbers that appear at least twice.
- For $k > 0$, it is efficient to use a hash set or a hash map to check if each number's complement ($\text{number} + k$) exists.
- Uniqueness is ensured by processing each number only once from the set of unique numbers.

Space & Time

Time Complexity: $O(n)$, where n is the length of the array since we iterate over the array and then over the unique numbers.

Space Complexity: $O(n)$, for storing the frequency count or the unique elements in a hash map or hash set.

Solution

The solution first checks if k is negative, returning 0 immediately if true. For k equals 0, we count numbers that appear more than once using a frequency map. For k greater than 0, a set of unique numbers is created and for each number, we check if $(\text{number} + k)$ is also present in the set. Each valid case contributes to the result count, ensuring that only unique pairs are considered.

#923 3Sum With Multiplicity [Medium]

Key Insights

- Use a frequency counter for elements since $\text{arr}[i]$ is in the range $[0, 100]$.
- Iterate through all possible combinations of numbers x , y , and z with $x \leq y \leq z$.
- For each valid triplet (x, y, z) that sums to target, count the number of ways using combinatorial formulas:
- All distinct: $\text{count}[x] * \text{count}[y] * \text{count}[z]$.
- Two numbers the same: use $nC2$ for the repeated element.
- All three the same: use $nC3$.
- Use modulo arithmetic ($\text{MOD} = 10^9 + 7$) at every step to avoid overflow.

Space & Time

Time Complexity: $O(M^2)$, where $M = 101$ (the range of possible numbers), which is efficient given the constraints.

Space Complexity: $O(M)$ for the frequency array.

Solution

The solution first counts the frequency of each number in the array. Then it iterates through all valid triplets (x, y, z) (with $x \leq y \leq z$) and checks if they sum up to the target. Depending on whether x, y , and z are distinct or have duplicates, the combination count is computed accordingly:

- If x, y , and z are all the same, compute the combination as $nC3$.
- If only two are the same, compute as $nC2$ multiplied by the count of the third number.
- If all are distinct, use the direct product of the counts. This covers all cases while applying the modulo operation to the result.

#986 Interval List Intersections [Medium]

Key Insights

- Use two pointers to traverse both lists simultaneously.
- Determine the overlapping interval by taking the maximum of the start points and the minimum of the end points.
- If the overlapping condition ($\text{start} \leq \text{end}$) is met, add the intersection to the result.
- Move the pointer that has the smaller end value to explore further potential intersections efficiently.
- Achieve an overall time complexity of $O(m+n)$, where m and n are the lengths of the two interval lists.

Space & Time

Time Complexity: $O(m + n)$ where m and n are the lengths of `firstList` and `secondList` respectively.

Space Complexity: $O(1)$ extra space (excluding the space used for the output).

Solution

The solution uses a two pointers approach. Initialize two indices, one for each list, and iterate through both lists. For each pair of intervals, the potential intersection is computed by:

- Calculating the maximum of the two start values.
 - Calculating the minimum of the two end values. If the maximum start is less than or equal to the minimum end, there is an intersection, and it is added to the result list.
- The pointer corresponding to the interval with the smaller end value is then incremented since that interval cannot intersect with any further intervals from the other list. This process repeats until one of the lists is fully traversed.

#1055 Shortest Way to Form String [Medium]

Key Insights

- Check if every character in target exists in source; if not, the answer is -1 .
- Use a greedy two-pointer strategy: iterate over target while scanning source for matching characters.
- During each pass over source, match as many characters as possible from target.
- Count the number of passes (subsequences) required until the target is completely matched.
- An optimized approach may precompute indices for binary search; however, the basic greedy simulation is efficient for the given constraints.

Space & Time

Time Complexity: $O(n * m)$ in the worst-case, where n = length of source and m = length of target.

Space Complexity: $O(1)$ for the greedy simulation ($O(n)$ if additional data structures for binary search are used).

Solution

The solution uses a greedy two-pointer approach. We simulate the process of reading the target by repeatedly scanning through the source string. Each scan through source is treated as one subsequence concatenated to form the target. A pointer in the target moves forward whenever a matching character is found in source. If a complete pass through source does not advance the target pointer, then it is impossible to form the target and we return -1 . The algorithm counts the number of passes required until the target is fully matched.

#2563 Count the Number of Fair Pairs [Medium]

Key Insights

- Sorting the array simplifies searching for pairs with required sum limits.
- For each element, binary search is used to locate:
 - The first index where the complement makes the sum $\geq$ lower.
 - The last index where the complement makes the sum $\leq$ upper.
- This avoids the need for a nested loop through the entire array, yielding a more efficient solution.

Space & Time

Time Complexity: $O(n \log n)$, primarily due to sorting and (for each element) binary search operations.

Space Complexity: $O(n)$ if sorting creates a copy; $O(1)$ additional space if sorting in-place.

Solution

The solution starts by sorting the input array. For each element at index i in the sorted array, we search for indices j (where $j > i$) such that the sum of $\text{nums}[i]$ and $\text{nums}[j]$ falls between lower and upper. Two binary search operations are performed:

– To find the smallest index j where $\text{nums}[i] + \text{nums}[j] \geq \text{lower}$. – To find the largest index j where $\text{nums}[i] + \text{nums}[j] \leq \text{upper}$. Subtracting the two positions (and summing the counts for each i) gives the total number of fair pairs. Edge cases (like no valid pair) are automatically handled by the binary search approach.

MEDIUM

Kth Largest Element in an Array

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Divide and Conquer](#) · [Sorting](#) · [Heap](#) · [Quickselect](#)

Lists: Grind 169

Problem:

Given an integer array `nums` and an integer `k`, return the `k`th largest element in the array.

Note that it is the `k`th largest element in the sorted order, not the `k`th distinct element.

Can you solve it without sorting?

Example 1:

Input: `nums = [3,2,1,5,6,4]`, `k = 2`

Output: 5

Example 2:

Input: `nums = [3,2,3,1,2,4,5,5,6]`, `k = 4`

Output: 4

Constraints:

- $1 \leq k \leq \text{nums.length} \leq 105$
- $-104 \leq \text{nums}[i] \leq 104$

>> Brute Force [Heap] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def findKthLargest(self, nums, k):
        # Brute Force  $O(n \log n)$  - sort descending, index at k-1
        nums.sort(reverse=True)
        return nums[k - 1]
```

Python

Python

```

import heapq

def findKthLargest(nums, k):
    # Create a min-heap with the first k elements
    min_heap = nums[:k]
    heapq.heapify(min_heap) # O(k) time to build the initial heap

    # Process the remaining elements
    for num in nums[k:]:
        # If the current element is larger than the smallest in the heap, replace it
        if num > min_heap[0]:
            heapq.heapreplace(min_heap, num) # O(log k)
    # The smallest element in the heap is the kth largest overall
    return min_heap[0]

Meeting Rooms II

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Two Pointers](#) · [Greedy](#) · [Sorting](#) · [Heap](#)

Lists: Grind 169 | Premium 98

Problem:

Given an array of meeting time intervals intervals where intervals[i] = [starti, endi], return the minimum number of conference rooms required.

Example 1:

Input: intervals = [[0,30],[5,10],[15,20]]

Output: 2

Example 2:

Input: intervals = [[7,10],[2,4]]

Output: 1

Constraints:

- 1 <= intervals.length <= 104
- 0 <= starti < endi <= 106

MEDIUM

Top K Frequent Elements

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Divide and Conquer](#) · [Sorting](#) · [Heap](#) · [Bucket Sort](#) · [Counting](#) · [Quickselect](#)

Lists: [Denny Zhang](#)

Problem:

Given an integer array `nums` and an integer `k`, return the `k` most frequent elements. You may return the answer in any order.

Example 1:

Input: nums = [1,1,1,2,2,3], k = 2

Output: [1,2]

Example 2:

Input: nums = [1], k = 1

Output: [1]

Example 3:

Input: nums = [1,2,1,2,1,2,3,1,3,2], k = 2

Output: [1,2]

Constraints:

- $1 \leq \text{nums.length} \leq 105$
- $-104 \leq \text{nums}[i] \leq 104$
- k is in the range [1, the number of unique elements in the array].
- It is guaranteed that the answer is unique.

Follow up: Your algorithm's time complexity must be better than $O(n \log n)$, where n is the array's size.

The Maze II

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [DFS](#) · [BFS](#) · [Graph](#) · [Matrix](#) · [Heap](#) · [Shortest Path](#)

Lists: Premium 98

Problem:

There is a ball in a maze with empty spaces (represented as 0) and walls (represented as 1). The ball can go through the empty spaces by rolling up, down, left or right, but it won't stop rolling until hitting a wall. When the ball stops, it could choose the next direction.

Given the $m \times n$ maze, the ball's start position and the destination, where $start = [startrow, startcol]$ and $destination = [destinationrow, destinationcol]$, return the shortest distance for the ball to stop at the destination. If the ball cannot stop at destination, return -1.

The distance is the number of empty spaces traveled by the ball from the start position (excluded) to the destination (included).

You may assume that the borders of the maze are all walls (see examples).

Example 1:

Input: maze = `[[0,0,1,0,0],[0,0,0,0,0],[0,0,0,1,0],[1,1,0,1,1],[0,0,0,0,0]]`, start = `[0,4]`, destination = `[4,4]`

Output: 12

Explanation: One possible way is : left -> down -> left -> down -> right -> down -> right.
The length of the path is $1 + 1 + 3 + 1 + 2 + 2 + 2 = 12$.

Example 2:

Input: maze = `[[0,0,1,0,0],[0,0,0,0,0],[0,0,0,1,0],[1,1,0,1,1],[0,0,0,0,0]]`, start = `[0,4]`, destination = `[3,2]`

Output: `-1`

Explanation: There is no way for the ball to stop at the destination. Notice that you can pass through the destination but you cannot stop there.

Example 3:

Input: maze = `[[0,0,0,0,0],[1,1,0,0,1],[0,0,0,0,0],[0,1,0,0,1],[0,1,0,0,0]]`, start = `[4,3]`, destination = `[0,1]`

Output: `-1`

Constraints:

- `m == maze.length`
- `n == maze[i].length`
- `1 <= m, n <= 100`
- `maze[i][j]` is 0 or 1.
- `start.length == 2`
- `destination.length == 2`
- `0 <= startrow, destinationrow < m`
- `0 <= startcol, destinationcol < n`
- Both the ball and the destination exist in an empty space, and they will not be in the same position initially.
- The maze contains at least 2 empty spaces.

Task Scheduler

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Hash Table](#) · [Greedy](#) · [Heap](#) · [Counting](#)

Lists: Grind 169

Problem:

You are given an array of CPU tasks, each labeled with a letter from A to Z, and a number n. Each CPU interval can be idle or allow the completion of one task. Tasks can be completed in any order, but there's a constraint: there has to be a gap of at least n intervals between two tasks with the same label.

Return the minimum number of CPU intervals required to complete all tasks.

Example 1:

Input: tasks = ["A","A","A","B","B","B"], n = 2

Output: 8

Explanation: A possible sequence is: A -> B -> idle -> A -> B -> idle -> A -> B.

After completing task A, you must wait two intervals before doing A again. The same applies to task B. In the 3rd interval, neither A nor B can be done, so you idle. By the 4th interval, you can do A again as 2 intervals have passed.

Example 2:

Input: tasks = ["A","C","A","B","D","B"], n = 1

Output: 6

Explanation: A possible sequence is: A -> B -> C -> D -> A -> B.

With a cooling interval of 1, you can repeat a task after just one other task.

Example 3:

Input: tasks = ["A","A","A","B","B","B"], n = 3

Output: 10

Explanation: A possible sequence is: A -> B -> idle -> idle -> A -> B -> idle -> idle -> A -> B.

There are only two types of tasks, A and B, which need to be separated by 3 intervals. This leads to idling twice between repetitions of these tasks.

Constraints:

- $1 \leq \text{tasks.length} \leq 104$
- `tasks[i]` is an uppercase English letter.
- $0 \leq n \leq 100$

Find K Closest Elements

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Binary Search](#) · [Sorting](#) · [Heap](#) · [Two Pointers](#)

Lists: Grind 169

Problem:

Given a sorted integer array *arr*, two integers *k* and *x*, return the *k* closest integers to *x* in the array. The result should also be sorted in ascending order.

An integer *a* is closer to *x* than an integer *b* if:

- $|a - x| < |b - x|$, or
- $|a - x| == |b - x|$ and $a < b$

Example 1:

Input: *arr* = [1,2,3,4,5], *k* = 4, *x* = 3

Output: [1,2,3,4]

Example 2:

Input: *arr* = [1,1,2,3,4,5], *k* = 4, *x* = -1

Output: [1,1,2,3]

Constraints:

- $1 \leq k \leq \text{arr.length}$
- $1 \leq \text{arr.length} \leq 104$
- *arr* is sorted in ascending order.
- $-104 \leq \text{arr}[i], x \leq 104$

Cheapest Flights Within K Stops

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Dynamic Programming](#) · [DFS](#) · [BFS](#) · [Graph](#) · [Heap](#)

Lists: Grind 169

Problem:

There are n cities connected by some number of flights. You are given an array `flights` where `flights[i] = [fromi, toi, pricei]` indicates that there is a flight from city `fromi` to city `toi` with cost `pricei`.

You are also given three integers `src`, `dst`, and `k`, return the cheapest price from `src` to `dst` with at most `k` stops. If there is no such route, return `-1`.

Example 1:

Input: $n = 4$, $flights = [[0,1,100],[1,2,100],[2,0,100],[1,3,600],[2,3,200]]$, $src = 0$, $dst = 3$, $k = 1$

Output: 700

Explanation:

The graph is shown above.

The optimal path with at most 1 stop from city 0 to 3 is marked in red and has cost $100 + 600 = 700$.

Note that the path through cities $[0,1,2,3]$ is cheaper but is invalid because it uses 2 stops.

Example 2:

Input: $n = 3$, $flights = [[0,1,100],[1,2,100],[0,2,500]]$, $src = 0$, $dst = 2$, $k = 1$

Output: 200

Explanation:

The graph is shown above.

The optimal path with at most 1 stop from city 0 to 2 is marked in red and has cost $100 + 100 = 200$.

Example 3:

Input: $n = 3$, $flights = [[0,1,100],[1,2,100],[0,2,500]]$, $src = 0$, $dst = 2$, $k = 0$

Output: 500

Explanation:

The graph is shown above.

The optimal path with no stops from city 0 to 2 is marked in red and has cost 500.

Constraints:

- $2 \leq n \leq 100$
- $0 \leq \text{flights.length} \leq (n * (n - 1) / 2)$
- $\text{flights}[i].\text{length} == 3$
- $0 \leq \text{fromi}, \text{toi} < n$
- $\text{fromi} \neq \text{toi}$
- $1 \leq \text{pricei} \leq 104$
- There will not be any multiple flights between two cities.
- $0 \leq \text{src}, \text{dst}, k < n$
- $\text{src} \neq \text{dst}$

K Closest Points to Origin

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Math](#) · [Divide and Conquer](#) · [Sorting](#) · [Heap](#)

Lists: Grind 169

Problem:

Given an array of points where $\text{points}[i] = [x_i, y_i]$ represents a point on the X-Y plane and an integer k , return the k closest points to the origin $(0, 0)$.

The distance between two points on the X-Y plane is the Euclidean distance (i.e., $\sqrt{(x_1 - x_2)^2 + (y_1 - y_2)^2}$).

You may return the answer in any order. The answer is guaranteed to be unique (except for the order that it is in).

Example 1:

Input: points = [[1,3],[-2,2]], k = 1

Output: [[-2,2]]

Explanation:

The distance between (1, 3) and the origin is $\sqrt{10}$.

The distance between (-2, 2) and the origin is $\sqrt{8}$.

Since $\sqrt{8} < \sqrt{10}$, (-2, 2) is closer to the origin.

We only want the closest k = 1 points from the origin, so the answer is just [[-2,2]].

Example 2:

Input: points = [[3,3],[5,-1],[-2,4]], k = 2

Output: [[3,3],[-2,4]]

Explanation: The answer [[-2,4],[3,3]] would also be accepted.

Constraints:

- $1 \leq k \leq \text{points.length} \leq 104$
- $-104 \leq x_i, y_i \leq 104$

Campus Bikes

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Greedy](#) · [Sorting](#) · [Heap](#)

Lists: Premium 98

Problem:

On a campus represented on the X-Y plane, there are n workers and m bikes, with $n \leq m$.

You are given an array `workers` of length n where `workers[i] = [xi, yi]` is the position of the i th worker. You are also given an array `bikes` of length m where `bikes[j] = [xj, yj]` is the position of the j th bike. All the given positions are unique.

Assign a bike to each worker. Among the available bikes and workers, we choose the (`workeri`, `bikej`) pair with the shortest Manhattan distance between each other and assign the bike to that

worker.

If there are multiple (worker_i, bike_j) pairs with the same shortest Manhattan distance, we choose the pair with the smallest worker index. If there are multiple ways to do that, we choose the pair with the smallest bike index. Repeat this process until there are no available workers.

Return an array answer of length n, where answer[i] is the index (0-indexed) of the bike that the ith worker is assigned to.

The Manhattan distance between two points p1 and p2 is $\text{Manhattan}(p1, p2) = |p1.x - p2.x| + |p1.y - p2.y|$.

Example 1:

Input: workers = [[0,0],[2,1]], bikes = [[1,2],[3,3]]

Output: [1,0]

Explanation: Worker 1 grabs Bike 0 as they are closest (without ties), and Worker 0 is assigned Bike 1. So the output is [1, 0].

Example 2:

Input: workers = [[0,0],[1,1],[2,0]], bikes = [[1,0],[2,2],[2,1]]

Output: [0,2,1]

Explanation: Worker 0 grabs Bike 0 at first. Worker 1 and Worker 2 share the same distance to Bike 2, thus Worker 1 is assigned to Bike 2, and Worker 2 will take Bike 1. So the output is [0,2,1].

Constraints:

- $n == \text{workers.length}$
- $m == \text{bikes.length}$
- $1 \leq n \leq m \leq 1000$
- $\text{workers}[i].\text{length} == \text{bikes}[j].\text{length} == 2$
- $0 \leq x_i, y_i < 1000$
- $0 \leq x_j, y_j < 1000$
- All worker and bike locations are unique.

MEDIUM

Minimum Cost to Connect Sticks

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Greedy](#) · [Heap](#)

Lists: Premium 98

Problem:

You have some number of sticks with positive integer lengths. These lengths are given as an array `sticks`, where `sticks[i]` is the length of the *i*th stick.

You can connect any two sticks of lengths *x* and *y* into one stick by paying a cost of *x* + *y*. You must connect all the sticks until there is only one stick remaining.

Return the minimum cost of connecting all the given sticks into one stick in this way.

Example 1:

Input: `sticks = [2,4,3]`

Output: 14

Explanation: You start with `sticks = [2,4,3]`.

1. Combine sticks 2 and 3 for a cost of $2 + 3 = 5$. Now you have `sticks = [5,4]`.

2. Combine sticks 5 and 4 for a cost of $5 + 4 = 9$. Now you have `sticks = [9]`.

There is only one stick left, so you are done. The total cost is $5 + 9 = 14$.

Example 2:

Input: `sticks = [1,8,3,5]`

Output: 30

Explanation: You start with `sticks = [1,8,3,5]`.

1. Combine sticks 1 and 3 for a cost of $1 + 3 = 4$. Now you have `sticks = [4,8,5]`.

2. Combine sticks 4 and 5 for a cost of $4 + 5 = 9$. Now you have `sticks = [9,8]`.

3. Combine sticks 9 and 8 for a cost of $9 + 8 = 17$. Now you have `sticks = [17]`.

There is only one stick left, so you are done. The total cost is $4 + 9 + 17 = 30$.

Example 3:

Input: `sticks = [5]`

Output: 0

Explanation: There is only one stick, so you don't need to do anything. The total cost is 0.

Constraints:

- $1 \leq \text{sticks.length} \leq 104$
- $1 \leq \text{sticks}[i] \leq 104$

Diagonal Traverse II

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Sorting](#) · [Heap](#)

Problem:

Given a 2D integer array `nums`, return all elements of `nums` in diagonal order as shown in the below images.

Example 1:

Input: `nums = [[1,2,3],[4,5,6],[7,8,9]]`

Output: `[1,4,2,7,5,3,8,6,9]`

Example 2:

Input: `nums = [[1,2,3,4,5],[6,7],[8],[9,10,11],[12,13,14,15,16]]`

Output: `[1,6,2,8,7,3,9,4,12,10,5,13,11,14,15,16]`

Constraints:

- $1 \leq \text{nums.length} \leq 105$
- $1 \leq \text{nums}[i].\text{length} \leq 105$
- $1 \leq \sum(\text{nums}[i].\text{length}) \leq 105$
- $1 \leq \text{nums}[i][j] \leq 105$

[*] Heap — Pattern Solution (stored optimal)

Python

```
def findDiagonalOrder(nums):
    # Use a dictionary to collect elements by their diagonal key (i + j)
    from collections import defaultdict
    diagonals = defaultdict(list)

    # Iterate over each row and its elements
    for i, row in enumerate(nums):
        for j, value in enumerate(row):
            # Insert at the beginning to achieve the desired order for the diagonal
            diagonals[i + j].insert(0, value)

    result = []
    # Process the diagonals in order of increasing key
    for key in sorted(diagonals.keys()):
        result.extend(diagonals[key])
    return result

# Example usage:
# nums = [[1,2,3],[4,5,6],[7,8,9]]
# print(findDiagonalOrder(nums)) # Output: [1,4,2,7,5,3,8,6,9]
```

C++

```
#include <vector>
#include <unordered_map>
#include <algorithm>
using namespace std;

vector<int> findDiagonalOrder(vector<vector<int>>& nums) {
    // Map from diagonal key to vector of integers
    unordered_map<int, vector<int>> diagonals;
    int maxKey = 0;

    // Iterate over each element in the 2D vector
    for (int i = 0; i < nums.size(); i++) {
        for (int j = 0; j < nums[i].size(); j++) {
            int key = i + j;
            maxKey = max(maxKey, key);
            // Insert at the beginning of the corresponding vector to achieve reverse order
            diagonals[key].insert(diagonals[key].begin(), nums[i][j]);
        }
    }

    vector<int> result;
    // Iterate through keys from 0 to maxKey
    for (int key = 0; key <= maxKey; key++) {
        if (diagonals.count(key)) {
            for (int value : diagonals[key]) {

```

```

        result.push_back(value);
    }
}
return result;
}

// Example usage:
// int main() {
//     vector<vector<int>> nums = {{1,2,3},{4,5,6},{7,8,9}};
//     vector<int> result = findDiagonalOrder(nums);
//     // result should be: [1,4,2,7,5,3,8,6,9]
//     return 0;
// }

```

HARD

Merge k Sorted Lists

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Linked List](#) · [Divide and Conquer](#) · [Heap](#) · [Merge Sort](#)

Lists: Grind 169

Problem:

You are given an array of k linked-lists lists, each linked-list is sorted in ascending order.

Merge all the linked-lists into one sorted linked-list and return it.

Example 1:

```

Input: lists = [[1,4,5],[1,3,4],[2,6]]
Output: [1,1,2,3,4,4,5,6]
Explanation: The linked-lists are:
[
  1->4->5,
  1->3->4,
  2->6
]
merging them into one sorted linked list:
1->1->2->3->4->4->5->6

```

Example 2:

```

Input: lists = []
Output: []

```

Example 3:

```

Input: lists = [[]]
Output: []

```

Constraints:

- $k == \text{lists.length}$
- $0 \leq k \leq 104$
- $0 \leq \text{lists}[i].\text{length} \leq 500$
- $-104 \leq \text{lists}[i][j] \leq 104$

- `lists[i]` is sorted in ascending order.
- The sum of `lists[i].length` will not exceed 104.

HARD

The Skyline Problem

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Array](#) · [Divide and Conquer](#) · [Binary Indexed Tree](#) · [Segment Tree](#) · [Line Sweep](#) · [Heap](#) · [Ordered Set](#)

Lists: Denny Zhang

Problem:

A city's skyline is the outer contour of the silhouette formed by all the buildings in that city when viewed from a distance. Given the locations and heights of all the buildings, return the skyline formed by these buildings collectively.

The geometric information of each building is given in the array `buildings` where `buildings[i] = [lefti, righti, heighti]`:

- `lefti` is the x coordinate of the left edge of the `i`th building.

- `righti` is the x coordinate of the right edge of the *i*th building.
- `heighti` is the height of the *i*th building.

You may assume all buildings are perfect rectangles grounded on an absolutely flat surface at height 0.

The skyline should be represented as a list of "key points" sorted by their x-coordinate in the form `[[x1,y1],[x2,y2],...]`. Each key point is the left endpoint of some horizontal segment in the skyline except the last point in the list, which always has a y-coordinate 0 and is used to mark the skyline's termination where the rightmost building ends. Any ground between the leftmost and rightmost buildings should be part of the skyline's contour.

Note: There must be no consecutive horizontal lines of equal height in the output skyline. For instance, `[..., [2,3], [4,5], [7,5], [11,5], [12,7], ...]` is not acceptable; the three lines of height 5 should be merged into one in the final output as such: `[..., [2,3], [4,5], [12,7], ...]`

Example 1:

Input: `buildings = [[2,9,10],[3,7,15],[5,12,12],[15,20,10],[19,24,8]]`

Output: `[[2,10],[3,15],[7,12],[12,0],[15,10],[20,8],[24,0]]`

Explanation:

Figure A shows the buildings of the input.

Figure B shows the skyline formed by those buildings. The red points in figure B represent the key points in the output list.

Example 2:

Input: `buildings = [[0,2,3],[2,5,3]]`

Output: `[[0,3],[5,0]]`

Constraints:

- $1 \leq \text{buildings.length} \leq 104$
- $0 \leq \text{lefti} < \text{righti} \leq 231 - 1$
- $1 \leq \text{heighti} \leq 231 - 1$
- `buildings` is sorted by `lefti` in non-decreasing order.

>> Brute Force [Heap] Interview Prep

Python

```
# Brute Force Approach
class Solution:
    def getSkyline(self, buildings):
        # Brute Force O(n log n) - sort repeatedly instead of heap
        data = list(buildings)
        result = []
        for _ in range(k):
            data.sort()
            result.append(data.pop(0))
        return result
```

Python

Python

```
import heapq

def getSkyline(buildings):
    # List to store all events: (x, height, right)
    events = []
    # Create events for all buildings: left edge (start) and right edge (end)
    for left, right, height in buildings:
        # For the start point, height is negative for proper sorting (start events come before end events)
        events.append((left, -height, right))
        # For the end point, height is 0 to indicate removal of building from active heap
        events.append((right, 0, 0))

    # Sort events by x coordinate.
    events.sort()

    # Max heap to store active buildings (using negative heights)
    result = []
    # Initialize the heap with a dummy building of height 0 that extends infinitely
    heap = [(0, float('inf'))]

    for x, neg_height, right in events:
        # Remove buildings from the heap that have ended by current x.
        while heap and heap[0][1] <= x:
            heapq.heappop(heap)

        # If event is a start event (neg_height != 0), push it into the heap.
        if neg_height != 0:
            heapq.heappush(heap, (neg_height, right))

        # Current highest building height is at the top of the heap
        current_height = -heap[0][0]
        # If the result is empty or current height differs from last recorded height, add a new key point.
        if not result or current_height != result[-1][1]:
            result.append([x, current_height])

    return result

# Example usage:

HARD

Closest Binary Search Tree Value II

[LeetCode](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [Stack](#) · [Tree](#) · [DFS](#) · [BST](#) · [Heap](#)

Lists: Premium 98

Problem:

Given the root of a binary search tree, a target value, and an integer k, return the k values in the BST that are closest to the target. You may return the answer in any order.

You are guaranteed to have only one unique set of k values in the BST that are closest to the target.

Example 1:

Input: root = [4,2,5,1,3], target = 3.714286, k = 2
Output: [4,3]

Example 2:

Input: root = [1], target = 0.000000, k = 1
Output: [1]

Constraints:

- The number of nodes in the tree is n.
- $1 \leq k \leq n \leq 104$.
- $0 \leq \text{Node.val} \leq 109$
- $-109 \leq \text{target} \leq 109$

Follow up: Assume that the BST is balanced. Could you solve it in less than $O(n)$ runtime (where n = total nodes)?

HARD

Find Median from Data Stream

[LeetDoocs](#) · [SimplyLeet](#) · [WalkCC](#) · [LeetCode](#) · [Editorial](#)

[Two Pointers](#) · [Design](#) · [Sorting](#) · [Heap](#)

Lists: Grind 169

Problem:

The median is the middle value in an ordered integer list. If the size of the list is even, there is no middle value, and the median is the mean of the two middle values.

- For example, for arr = [2,3,4], the median is 3.
- For example, for arr = [2,3], the median is $(2 + 3) / 2 = 2.5$.

Implement the MedianFinder class:

- MedianFinder() initializes the MedianFinder object.
- void addNum(int num) adds the integer num from the data stream to the data structure.
- double findMedian() returns the median of all elements so far. Answers within 10⁻⁵ of the actual answer will be accepted.

Example 1:

Input

```
["MedianFinder", "addNum", "addNum", "findMedian", "addNum", "findMedian"]  
[[], [1], [2], [], [3], []]
```

Output

```
[null, null, null, 1.5, null, 2.0]
```

Explanation

```
MedianFinder medianFinder = new MedianFinder();  
medianFinder.addNum(1); // arr = [1]  
medianFinder.addNum(2); // arr = [1, 2]  
medianFinder.findMedian(); // return 1.5 (i.e., (1 + 2) / 2)  
medianFinder.addNum(3); // arr[1, 2, 3]  
medianFinder.findMedian(); // return 2.0
```

Constraints:

- $-105 \leq \text{num} \leq 105$
- There will be at least one element in the data structure before calling findMedian.
- At most $5 * 10^4$ calls will be made to addNum and findMedian.

Follow up:

- If all integer numbers from the stream are in the range $[0, 100]$, how would you optimize your solution?
- If 99% of all integer numbers from the stream are in the range $[0, 100]$, how would you optimize your solution?

Python

Python

```
import heapq  
  
class MedianFinder:  
    def __init__(self):  
        # max-heap for the lower half (store negatives to simulate max-heap)  
        self.lowerHalf = []  
        # min-heap for the upper half  
        self.upperHalf = []  
  
    def addNum(self, num: int) -> None:  
        # Push to max-heap (simulate by pushing negative)  
        heapq.heappush(self.lowerHalf, -num)  
        # Ensure every element in lowerHalf is <= every element in upperHalf  
        # Move maximum of lowerHalf to upperHalf  
        heapq.heappush(self.upperHalf, -heapq.heappop(self.lowerHalf))  
  
        # Balance the heaps: if upperHalf exceeds lowerHalf in size  
        if len(self.upperHalf) > len(self.lowerHalf):  
            heapq.heappush(self.lowerHalf, -heapq.heappop(self.upperHalf))  
  
    def findMedian(self) -> float:  
        # If both heaps are balanced, median is average of both heaps' top elements  
        if len(self.lowerHalf) == len(self.upperHalf):  
            return (-self.lowerHalf[0] + self.upperHalf[0]) / 2.0  
        # Otherwise, median is the top element of the larger heap
```

```

        return -self.lowerHalf[0]

# Example usage:
# medianFinder = MedianFinder()
# medianFinder.addNum(1)
# medianFinder.addNum(2)
# print(medianFinder.findMedian()) # Outputs 1.5
# medianFinder.addNum(3)
# print(medianFinder.findMedian()) # Outputs 2.0

```

Python
